Jaundice—One of the most important clinical signs of hepatic disease is jaundice, and the study of its pathogenesis has been instructive and stimulating. The rudiments of the present conception may be briefly stated as follows. Bilirubin, derived from hemoglobin, is brought in the circulation to the liver cells, which excrete it along with other constituents of the bile into the bile canaliculi, whence it passes down the bile passages into the intestine. Here it is changed to urobilin or to urobilinogen, a part of which is absorbed, carried back to the liver and excreted again into the bile. When the excretory function of the liver is depressed the urobilin often accumulates to some extent in the blood stream and may be excreted by the kidneys into the urine. Urobilinogenuria is hence regarded as an indication of depressed activity on the part of the liver. Rich¹ has emphasized the division of jaundice into two main types, retention jaundice and regurgitation jaundice.

In retention jaundice the bilirubin circulating in the blood stream may not all be excreted by the liver cells and accumulates in the blood. Under these circumstances the bilirubin seems to be bound in some way, perhaps to the plasma proteins, gives an indirect van den Bergh reaction and does not pass through the kidneys into the urine (acholuric jaundice). Retention jaundice associated with milder forms of injury to the liver, cloudy swelling or atrophy of cells, is due to an increased formation of bilirubin, together with a depressed excretory function of the liver, due in turn to different factors, particularly to anoxemia and to fever. This milder type of jaundice and of hepatic injury is associated with such diseases as the hemolytic anemias, congestive heart failure, malaria and lobar pneumonia, in which the injury to the liver and the retention jaundice are comparatively insignificant features of the illness.

In regurgitation jaundice, on the other hand, the bilirubin is excreted by the liver cells and then, through rupture of the bile canaliculi, escapes into the tissue spaces and blood sinusoids of the liver by reason either of obstruction of the larger bile ducts or of necrosis of the liver cells. In this case, not only bilirubin but whole bile gets into the blood stream. The bile pigment now is not bound, it gives a direct van den Bergh reaction and it is readily excreted by the kidneys into the urine (choluric jaundice). This is the type of jaundice associated with the major acute hepatic disorders and with biliary cirrhosis. Either type of jaundice may occur in the common portal cirrhosis. The careful observation of the occurrence of bile pigments in the tissues, in the

Read in the Medical Division of the General Scientific Meetings at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 8, 1937.

urine and in the intestinal tract and laboratory studies of the qualitative and quantitative relationships of bilirubin in the blood are valuable diagnostic features in hepatic disease

Portal Obstruction and Water Retention—The presence of ascites of even moderate degree and of a palpable spleen are usually obvious clinical conditions. The clinical study of the ascitic fluid, notably of the color, the specific gravity, the albumin content, estimated by means of an Esbach tube, and the cellular content, can be made in the simplest laboratory. In addition to the ascites, or even in its absence, one may find other evidence of portal obstruction in the development of collateral venous channels, dilated veins may be readily visible on the thoracic and abdominal walls, dilatation of hemorrhoidal veins may be noted, although they are not especially common with cirrhosis, and by the use of a thick barium paste esophageal varices may readily be demonstrated by roentgenography. The last-named test may well be performed early in the examination, for a positive result may suggest the inadvisability of passing a stomach tube. The presence of blood in the vomitus or in the stools may indicate the presence of esophageal varices. The marked increase in the caliber and in the number of anastomoses between the portal and the caval venous systems is of course an attempt at a compensatory process. So far as the ascites is concerned, the compensation if successful is also quite favorable. As with other attempts at pathologic adaptation, however, the adaptation is not always useful, and it may be harmful in this case in two ways, namely, in the promotion of the risk of hemorrhage from dilated and weakened veins and in the shunting of the liver out of the portal circulation, the body thus being deprived of important services on the part of the liver.

Until recently it was generally assumed that ascites in hepatic disease was due entirely to obstruction of the portal radicles within the liver and that the dependent edema sometimes noted was caused by the pressure of the ascitic fluid on the vena cava. It is now realized that ascites does not account for all the water retention. Observers have noted the occurrence of such retention in both acute and chronic hepatic disease in the absence of ascites. Jones² has emphasized the occurrence of spontaneous diuresis at a certain stage of acute and subacute hepatic disease, as this is followed usually by rapid clinical improvement he presented it as a valuable and favorable prognostic indication.

One probable cause of the disturbance in the fluid balance in disorders of the liver may be related to the blood plasma proteins. Several observers have noted some disturbance of the plasma proteins in various types of hepatic disease. This change is especially notable in cirrhosis, in which the total plasma proteins are reduced and particularly the albumin fraction. The globulin fraction may be less reduced, or it may actually be increased, with a resulting inversion of the albumin-globulin ratio. In several cases of cirrhosis reported the albumin content of the blood plasma was usually below 2.5 Gm per hundred cubic centimeters. Several students of this problem believe that the hypoalbuminemia may itself be an indication of hepatic insufficiency. It does not behave like the simple loss of protein through inanition or dietary deficiency. For Myers and Keefer³ could not increase the plasma proteins in their

cirrhotic patients by high protein diets and, further more, the reduction in the serum albumin bears no definite relationship to the amount of albumin lost in the ascitic fluid.

Changes in the Size, Shape and Consistency of the Liver—These changes are of value primarily in calling attention to a pathologic change in the organ. The size of the liver in portal cirrhosis is usually increased in spite of the term atrophic cirrhosis. Particularly in the earlier stages the liver is apt to be enlarged, and its increased consistency makes this factor more readily available to the examiner. In toxic cirrhosis the liver may be definitely decreased in size. The size of the cirrhotic liver is determined not only by the disappearance of parenchymatous cells and the contraction of fibrous tissue that tend to decrease its size but by the storage of fats and the presence of inflammatory products that tend to make the organ larger.

Tests of Hepatic Function—Tests have been devised for the study of many of the functions of the liver, including those having to do with the metabolism of carbohydrates, of proteins and of fats, its power of detoxication and its ability to excrete certain substances into the bile. Some of these tests have come into fairly general use, and this may be taken, to some extent, as a measure of their helpfulness. In view of the great reserve power in all these functions the tests are of possible importance only when lesions are widespread or diffuse throughout the liver. They usually have negative results, for example, in the diagnosis of such conditions as solitary abscess or sparsely scattered metastases in the organ.

Of the many tests, those that deal with the liver's excretory functions seem to be of most help in cases of cirrhosis. In cases of jaundice the study of the bile pigments in the urine, in the stool, in the duodenal contents and in the blood serum is distinctly helpful. The indirect and direct reactions of the van den Bergh test for bilirubin in the blood serum distinguish between retention and regurgitation jaundice. A positive van den Bergh reaction with a slight but definite increase in the serum bilirubin may reveal the presence of subclinical jaundice. By means of the quantitative van den Bergh test or the simpler icterus index test the amount of the bilirubin in the blood serum can be determined from time to time, and its increase or decrease may be of considerable value in the continued observation of a case.

In cases without jaundice, the study of the behavior of injected bilirubin indicates that it may prove to be a more delicate test than most others that have been devised. It will be noted that the substance used is one normally and constantly being excreted by the liver and its use in an excretory test is therefore quite rational. So far the expense of the pure bilirubin and the somewhat involved technic have militated against its general usefulness.

Other excretory tests are based on the fact that several dyes (phenoltetrachlorophthalein, bromsulphalein, bengal rose) have been found that are excreted entirely or almost entirely into the bile. The dyes are also recognizable quantitatively when retained in the blood serum and are measured by colorimetric methods. Perhaps the most widely used of these tests is the bromsulphalein test. It has attained a certain popularity and is of particular value in the absence of jaundice or when the degree of jaundice is minimal. Obviously when there is marked jaundice the retention of the dye in the serum may merely parallel the degree of jaundice.

² Jones C. M. and Eaton F. B. Spontaneous Diuresis in Acute and Subacute Hepatic Disease. *England J. Med.* 213: 907-918 (Nov. 1935).
³ Myers W. K. and Keefer C. Ascites and Edema in Cirrhosis of the Liver. *Am. J. Med.* 1: 1-5 (March) 1935.

Sometimes, however, a marked disproportion in the retention of dye is found in cases of small degrees of jaundice. In the performance of the test a dose of 5 mg. of the dye per kilogram of body weight is injected intravenously, at the end of one-half hour a specimen of blood is obtained and examined, the retention of a measurable quantity of the dye, 10 per cent or more, is considered definitely abnormal and indicative of damage to the liver.

Of the carbohydrate tests of hepatic function the galactose tolerance test may be of aid in diagnosis of the acute injury to the liver that precedes the development of toxic cirrhosis. In cases of marked jaundice there may be difficulty in the differentiation between diffuse necrosis of the liver and the jaundice due to obstruction of the common bile duct. The galactose test is of value especially in the early stages of the illness, when the destruction of liver cells, on the one hand, is at a maximum and when, on the other hand, the damaging effect of obstruction of ducts on liver cells is still slight. Other carbohydrate tests are occasionally used in cases of cirrhosis, namely, the levulose tolerance test and modifications of the dextrose tolerance test, but they usually give positive results only in advanced cases and in general seem less helpful than the excretory tests.

Methods based on the protein metabolism of the liver have not been strikingly helpful and are not widely used. If the changes in the blood plasma protein may be considered in the light of such metabolism they may be of value in the absence of other causes of hypoalbuminemia. The study of fat metabolism in this relationship is relatively new and not yet well evaluated.

TYPES OF CIRRHOSIS

Of the several types of cirrhosis, by far the commonest is the so-called common or portal cirrhosis, and with this type I am particularly interested in this paper. Next perhaps in frequency is the type called by Mallory⁴ toxic cirrhosis or cirrhosis of acute toxic origin. Of the relatively rarer types, the pigmentary cirrhotoses present quite separate problems and will not be considered at this time. By biliary cirrhosis is meant a chronic diffuse hepatic disease associated particularly with chronic jaundice and due either entirely to prolonged obstruction of ducts or to the combination of obstruction and infection of ducts. This type is also relatively uncommon, and it has a certain analogy to chronic pyelonephritis as a comparatively unusual cause of renal insufficiency. In both instances the problems of prophylaxis and of cure have to do with the avoidance or the amelioration of obstruction and infection in the respective excretory channels. At times there are definite surgical implications.

In cases of well developed ordinary portal cirrhosis the diagnosis is usually easy. The abdomen is distended with fluid, in spite of which the firm edges of the liver and of the spleen may be felt. The bulging abdomen is in striking contrast to the emaciation of the body elsewhere. There are the pinched saw face and the muddy or subicteric conjunctivae. Dilated veins on the thoracic and abdominal walls may be noted. There may be anorexia and nausea and perhaps vomiting, the tongue may be coated and the breath offensive. Hematemesis and melena may occur from oozing or rupture of an esophageal varix, there may be moderate or marked secondary anemia. Occasional spells of fever are not uncommon. The urine is rather scanty, is con-

centrated and contains urobilinogen. Mild jaundice may be obvious occasionally. An examination of the blood may show a positive van den Bergh reaction and a slight increase in the bilirubin content of the blood even in the absence of definite clinical jaundice. Such jaundice in cirrhosis is due not to a general obstruction of ducts, like that of a stone in the common duct, but to distortion and obstruction of small ducts here and there within the liver and may show varying degrees of severity. The blood may also show the characteristic changes in the plasma proteins. Excretory tests of hepatic function give definitely positive results. In the later stages there may be hypoglycemia, decreased fibrinogen content and all the evidences of extreme hepatic insufficiency. The earlier toxic symptoms include headache, general malaise, mild clouding of the sensorium and depression, later on delirium or drowsiness and coma are the striking features.

The cirrhosis of acute toxic origin may resemble clinically and pathologically the commoner portal type. It may develop soon or late after massive necrosis of

the liver, which is survived but after which the regeneration of liver cells takes place irregularly, many areas within the organ remain collapsed and become fibrosed and all the cells in many contiguous lobules are entirely destroyed.

It is known from many statistical reports on autopsies that a large proportion, perhaps one half, of the patients listed as having cirrhosis of the liver died of accident or some cause other than the cirrhosis. One cannot be sure in how many cases latent cirrhosis is well compensated and the patient reasonably safe in his hepatic health and how many patients may soon acquire signs and symptoms of cirrhosis. The fact, however, emphasizes the difficulties of early diagnosis and at the same time puts the physician on his mettle in making the attempt.

ETIOLOGY

In both the prevention of cirrhosis and the diagnosis of cases in the early stages, some consideration of the etiology is essential. In the acutely developing cases a single massive destructive lesion may suffice. The widely diversified list of possible agencies in the production of such lesions may be appreciated by study of a table like that published by Bockus and Tumen⁵ under the

⁴ Mallory F B. Cirrhosis of the Liver. Five Different Types of Lesions from Which It May Arise. Bull Johns Hopkins Hosp 22: 69 1911

⁵ Bockus H L and Tumen H J. Jaundice in Piersol G M. The Cyclopedia of Medicine Philadelphia F A Davis Company 1933 vol 7 p 588

title "Hepatocellular Jaundice," which is another name to indicate widespread necrotic lesions in the liver. In the commoner cases of portal cirrhosis with insidious onset and gradual progression there are presumably multiple small and frequently repeated insults to the liver cells, but there are no particular reasons to believe that the sources of these insults are different in kind from those capable of causing the more acute and massive lesions. In the case of acute hepatic disease there is the impression that one can divide the causes of the disturbance into direct exciting causes and predisposing causes, the direct causes being those listed in the table and the predisposing causes such factors as a depletion in the glycogen reserve of the liver, anoxemia, the presence of a preexistent chronic diffuse disease of the liver, pregnancy and the puerperium, toxic thyroid states and the presence of a syphilitic infection.

The etiologic factors in general of the insidious chronic cases are much less well understood, and one has distinct difficulty in separating possible exciting from possible predisposing causes, for example, it is believed that syphilis can directly cause the ordinary type of portal cirrhosis, and it is also believed that syphilis may be a predisposing factor in its development. Alcohol occupies a prominent place in the clinical mind as an etiologic agent in portal cirrhosis, which can quite correctly be called alcoholic cirrhosis in a large proportion of the cases, but there is no unanimity of opinion as to whether the alcohol is the directly poisoning agent or whether its chronic and persistent use predisposes the liver to damage by some other noxious substance.

The importance of syphilis and particularly of the treatment of this disease is being repeatedly emphasized now as a probable cause of cirrhosis. Statistics at present certainly do not show this relationship clearly, and some syphilographers are doubtful that the continuous treatment of syphilis over long periods (and particularly the use of arsphenamine) is an important factor in the development of chronic hepatic disease. Others, however, have repeatedly emphasized that it is, and Baldrige⁶ reported that of a series of thirty-six patients with cirrhosis one third had histories of treatment for syphilis. There is general agreement that in at least 25 per cent of the patients undergoing intensive antisyphilitic therapy there is some damage to the liver. The uncertainty concerns the production of chronic disease, for it is well known that the liver can recover promptly and completely from acute lesions. As an illustration of the possible importance of both syphilis and antisyphilitic therapy to the production of chronic hepatic disease, Kellogg, Epstein and Keri⁷ reported a high incidence (19 per cent) of abnormal hepatic function as shown by an excretion test (bengal rose) in a group of ninety patients with untreated syphilis. Antisyphilitic therapy caused transitory disturbances in hepatic function in five of twenty-nine patients originally having a normal function and caused further impairment in four of eighteen patients with initially abnormal function. Patients with initially abnormal hepatic function had they reported an increased tendency to have untoward reactions to antisyphilitic therapy.

DIAGNOSIS

In the attempt to make a diagnosis of cirrhosis of the liver in an early stage or in a late compensated case

6	Baldrige C W	The Relati	Am J M	1938	K	W	J	H	Treat

one cannot expect to attain scientific accuracy except in the rare instance in which biopsy can be done in the course of a laparotomy instituted for some other cause. There is no other definitive test. It is a true saying though none the less true, that before such a diagnosis of probability is possible one must have such an eventuality in mind, one must entertain the idea of chronic hepatic disease when consulted by a middle aged man who is evidently chronically but mildly ill or who gives a history of prolonged chronic alcoholism or of a syphilitic infection with persistent treatment. The interest in this possibility will be enhanced by a further history of malaise, loss of weight, "dyspepsia" and perhaps one or more episodes of slight jaundice. The finding of a firm palpable liver should then put one on the qui vive for further evidences of liver damage. In the painstaking history one should inquire for the various possible etiologic factors, including chemical poisons, vegetable poisons and bacterial and virus diseases. One will inquire carefully for symptoms so vague that they may have been almost forgotten by the patient, particularly transient feelings of fatigability, of anorexia, of occasional nausea and vomiting, especially in the morning, of abdominal pain or unrest or irregularity of the bowel.

The suggestion of cirrhosis may come in a quite different way when the patient's chief complaint is of the vomiting of blood or the passing of black stools. Careful inquiry may then elicit a report of the early symptoms mentioned, or the hematemesis may have occurred with little or no warning. The hemorrhage is not often repeated within a short time, and the considerable interval that usually elapses before the development of ascites affords an opportunity for the use of modern methods of treatment before the reserve power of the liver has approached its vanishing point. In the case of a middle aged man with hematemesis or melena, think of the possibility of cirrhosis as well as of a peptic ulcer.

After a careful physical examination that may reveal an enlarged and perhaps slightly tender liver and possibly slight evidence of portal obstruction, further tests may be helpful.

The van den Bergh reaction of the blood serum may disclose latent jaundice that was not noticeable otherwise.

Urobilinogen may be present in excess in the urine. The bromsulphalein test may show an abnormal retention of this dye in the blood serum.

The total blood proteins may be somewhat reduced in amount, although it is unlikely that the normal albumin-globulin ratio will be disturbed.

Particularly important, especially in cases in which there is a history of hemorrhage, is the x-ray examination of the lower end of the esophagus for dilated varices.

TREATMENT

In the institution of a therapeutic regimen for chronic diseases, a sine qua non is the satisfactory cooperation on the part of the patient, hence the psychotherapeutic approach, with encouragement, with full and complete explanations, must be primary. A situation arises sometimes, unfortunately, in which it seems necessary to frighten a patient and to frighten him badly before he can be persuaded to change his unhygienic habits. Unless the patient has a reasonable intelligence (not necessarily education) there is little hope of stopping the progress of the disease and building up a serviceable hepatic reserve.

The second step is to secure the complete elimination, as far as practicable, of potentially harmful agents. Alcohol comes to mind at once, and one realizes the difficulty of persuading the addicted to abstain. One will probably have less trouble in eliminating irritating foods, such as spices, condiments and pickles, that are ordinarily included in this category.

There is difference of opinion in regard to the therapeutic course to pursue when a patient with early cirrhosis is receiving or should receive antisyphilitic therapy. Most authorities advise beginning treatment with iodides and heavy metals, with a later tentative trial of arsphenamine in small doses. Moore⁸ emphasized the point that for patients without ascites the prognosis is good and for patients with ascites the prognosis is bad regardless of the type of treatment.

The diet must be adapted to prolonged use. Counsel of perfection should be mingled with judgment. Palatability and variety are important. The intake of protein may be kept down to about 1 Gm per kilogram of body weight. Although in view of much experimental work one might wish to eliminate meat entirely, it is probably wiser to permit its use in small portions two or three times a week. Meat extracts and beef broth should be eliminated. The chief protein requirements should come from vegetables and dairy products.

Of the fats, butter and cream should be permitted to enhance the palatability of the diet. Fried foods, fat meats and vegetable oils should be omitted.

A high carbohydrate diet is essential. It is the most important single agent conducive to building up the liver's resistance and adding to its reserve. The ideal should be to keep the liver cells constantly well supplied with glycogen. It is estimated by Althausen⁹ and others that the usual high carbohydrate diet will furnish from 250 to 300 Gm of dextrose daily. A theoretical quantity of from 500 to 550 Gm is desirable, and the additional amount may be served as pure dextrose in fruit juice between meals and before the patient retires at night. Cereals and other starchy vegetables loom large in such a diet. If there are unpleasant digestive symptoms the green vegetables may be prepared as purees. The dextrose may at times be disturbing and should then be omitted for a period or given during two days of each week.

The hygiene of rest and of exercise needs attention. The patient should avoid marked fatigue. There should be a brief period of rest, with the patient lying down, in the middle of the day, and he should spend nine hours in bed each night. Mild exercise, well within the patient's tolerance, may be permitted at once, and with improvement this should be gradually increased. Recreation and diversity of interests are thereby enhanced.

Certain accessory methods of therapy may be useful. Many physicians like to give iodides a thorough trial even in the absence of a positive Wassermann reaction or other evidence of syphilis. Small daily doses of calcium may be useful and would seem to me harmless. Certainly in some cases of more acute poisoning of the liver such as poisoning with carbon tetrachloride, the toxicity is attributed in part to guanidine compounds and the favorable effect of calcium to its union with these substances.

There are a number of reports relating to protective methods in experimental poisoning of the liver.

Cutler¹⁰ found that no type of diet would protect the liver tissue of his experimental animals from destruction by carbon tetrachloride but that diets rich in carbohydrates and in calcium were effectual in combating the degree of intoxication and the number of deaths secondary to the hepatic damage. Forbes, Neale and Sherer¹¹ described an aqueous solution of an alcoholic fraction of liver that protects animals against necrosis due to administration of chloroform or carbon tetrachloride. Their report is intriguing and may hold a certain amount of promise for the therapy of human diseases.

Particular situations may demand special attention. With bleeding esophageal varices, the esophagus must be kept at complete rest by the withholding of food or water by mouth and the administration of fluid and dextrose parenterally. Transfusions of blood may be advisable later. In considering the treatment of early cases one needs not go into the treatment of ascites. Early in the development of that symptom, however, one may accomplish a great deal by the moderate withholding of salt and of fluids and the use of ammonium chloride and mercurial diuretics such as salyrgan and mercupurin (the sodium salt of trimethylcyclopentane-dicarboxic acid-methoxy-mercury-allylamide-theophylline).

Finally, a physician and his patient should have regular conferences in which the details of the treatment are discussed and the patient's confidence and cooperation stimulated by judicious admonition and encouragement.

THE LASTING CURE OF EARLY PULMONARY TUBERCULOSIS

J. BURNS AMBERSON, JR., M.D.

NEW YORK

There are seven reasons for directing attention again to the early tuberculous lesion and its cure, to wit:

The nature of the early lesion is better understood now than ever before.

The time of life when the lesion is most likely to appear is more clearly defined.

The methods of diagnosing its presence have been developed and perfected.

The subsequent behavior of the early lesion and the ways of its healing or advancement are better known.

Most disabling and fatal tuberculosis originates in this lesion.

Knowledge of the methods of treatment and their proper selection and application is more accurate and reliable.

The far reaching and vastly superior results of proper and timely treatment of the early lesion are firmly established.

Today, as in previous decades, from 60 to 70 per cent, at least, of all tuberculous patients in this country are in an advanced stage of the disease when the diagnosis is made, their treatment is exceedingly costly in terms of money and other less tangible but more important values, and the results of treatment are, on the whole, unsatisfactory. Recovery involves a certain permanent loss of pulmonary function, a limitation of the

usual activities of life and a danger of relapse. Could the knowledge that has come slowly through years of experience and research be applied wisely and widely, this picture could be changed almost completely for the better. The early pulmonary lesion is one of the vital and focal points for the attack.

NATURE OF THE EARLY LESION

It is obvious that the small tuberculous lesion first discovered in the lung is not necessarily an early one. The line of thought will be more direct if I start with the lesion that is not only small but also recently developed. It may be caused by infection from without or by an extension from preexisting lesions, usually tiny or even microscopic, which, for a short or long time, have lain dormant and concealed. Previous examinations, therefore, may have revealed nothing abnormal except perhaps an apparently insignificant apical scar or a calcified hilar lymph node. The development of the early lesion, often called the early infiltration, may be rather abrupt, that is, within a week or a month, or it may be gradual with static periods of apparent quiescence. Rapidity of development, however, is one of its common characteristics. Pathologically it is a patch of tuberculous bronchopneumonia, occupying a section of the parenchyma usually not more than 2 or 3 cm in diameter, sometimes at the apex but more often just below. The patient has no symptoms or only slight to moderate constitutional ones, chiefly a loss of a few pounds of weight and a little undue fatigue. Fever is not usually detected, and cough, expectoration and bloody sputum are rare at this stage. In some cases a patch of fine râles may be heard directly over the small lesion, but more often the physical examination reveals nothing abnormal in the chest. The roentgenogram shows, as a rule, the small area of soft infiltration in one lung. Tubercle bacilli are not found in the sputum unless the lesion has caseated and broken into a bronchus, and this is not the condition at the very onset.

TIME OF APPEARANCE

Pulmonary tuberculosis has been known since Hippocrates to take its heaviest toll between the ages of 18 and 35. This relates to disability and fatality and only by inference to the time of development of the early lesion, which has been revealed more clearly in recent years through case finding surveys among apparently healthy people. No age is immune to this danger, but the peak of development has been found to be between adolescence and the late twenties. Periodic surveys among grade school pupils have not led to the discovery of many early infiltrations. In a particularly methodical study on the basis of annual examinations of a clerical force of about 10,000 women and 2,000 men between the ages of 18 and 42 at the home office of the Metropolitan Life Insurance Company, Fellows¹ found very definite trends. Between January 1932 and December 1936, clinical pulmonary tuberculosis developed in 142 previously healthy persons, of whom 83 per cent were between the ages of 18 and 27. Here, as in other studies, the incidence was relatively higher and rose to its peak earlier in young women.

DIAGNOSIS

As shown in previous studies—the early lesion will be discovered in only a small minority of cases unless

the disease is viewed as a community problem and organized searches for it are made periodically. The patient, having few or no symptoms of illness, does not seek the physician. Rather, the physician, in his capacity as a far seeing health officer, must seek the patient. Tuberculin testing and x-ray examination of the chest, wisely planned and applied, are indispensable parts of the diagnostic method. If the diagnosis is adequate, it will include not only a recording of the lesion but also an interpretation of its potential significance and the need for treatment. The small size of the infiltration, the lack of symptoms, and the failure to get confirmatory evidence in the finding of tubercle bacilli in the sputum often cloak the situation with a grossly undeserved aspect of innocence.

SUBSEQUENT BEHAVIOR OF THE LESION

The early infiltration may be absorbed almost completely, leaving behind a small scar, or it may spread, become caseated and liquefied at its center and ulcerate into a bronchus, whence other parts of the lung may become contaminated, the beginning of advanced tuberculosis. Absorption, if it occurs, is slow. The tendency to central caseation is a predominant one, varying in intensity and rapidity. After ulceration and excavation of the lesion occurs, the rate and extent of formation of secondary lesions vary within wide limits. Acute bilateral tuberculous bronchopneumonia may be set up within a few weeks. More often the extensions occur at irregular intervals, and gradually the case drifts into the confirmed chronic state. The eventual contamination and infection of the larynx, intestine and other related structures by the bacilliferous discharges from the pulmonary cavities is frequent.

The frequency of spontaneous healing of untreated early lesions is a matter for further investigation. The number of old apical scars discovered at autopsy testifies to the effectiveness of natural resistance in most people. But these scars may not and probably as a rule do not represent the residues of lesions as large or as acute as those I am considering and therefore should not be taken as a measure of the spontaneous healing capacity of the latter. This can be determined only by prolonged observation of untreated patients harboring such lesions. It undoubtedly varies according to many factors, including age, race, sex and complicating diabetes. According to Braun and Roulet,³ who have recently reviewed the European literature, the most optimistic observers estimate that as high as 40 per cent of the lesion may heal completely. I am reasonably certain, after ten years of special attention to the point, that the majority of early infiltrations developing in young people (and most of them do develop in young people, as stated) progress and undergo excavation if they are not promptly and properly treated.

MOST SERIOUS TUBERCULOSIS RELATED TO EARLY LESION

Since most patients have advanced disease when the diagnosis of tuberculosis is first made, the mode of development in the individual case is usually a matter for intelligent conjecture and inference. But sufficient information has been accumulated by the pathologists and from a study of pathogenesis in the living to warrant the conclusion that most disabling and fatal tuberculosis originates from the once innocent appearing early infiltration. An appreciation of this linkage has been lacking until recent years yet is one of the most

important and basic principles in treatment and control. The conception, to be complete, includes the element of time relationships, because, as stated, the extension from the early lesion may be rapid or slow, limited or wide, continuous or discontinuous. Connecting this conception with the evidence that most early pulmonary infiltrations put in their appearance between adolescence and the late twenties, it follows that advanced tuberculosis is unlikely to develop in a person past 30 unless he has acquired a considerable lesion before this age.

METHODS OF TREATMENT

Since the tendency is for the early lesion to caseate at its center fairly rapidly any treatment which prevents, retards or arrests this process would logically strike at a very vital point. Absorption and durable fibrosis can be expected only when caseous degeneration has not advanced greatly. Our knowledge is still too vague to permit speaking in precise terms about the many factors which stay the progress of caseation and favor healing. Clinical experience shows that they are deep rooted and include such things as circulatory tone, capillary permeability, endocrine balance, biochemical relationships and nervous, emotional and mental stability. In fact, in the presence of the early infiltration with little or no cavity formation, these general influences are of major importance and are the main basis of the rest cure. The situation is very different from the advanced case presenting a pulmonary cavity in which local mechanical factors are important and require artificial collapse of the lung to prevent further dissemination of the infection while healing proceeds. The great advantage of the rest cure in a sanatorium, especially for younger people, has been amply proved by clinical trial. The sooner and the more strictly this can be instituted, the more effective it is likely to be. In many cases the treatment of the first few weeks is the most important of all. In the case of a person under the age of 25 with an early infiltration, our practice at Bellevue Hospital is almost invariably to advise a period of strict bed rest, lasting from two to four months. Some older patients, especially those with indolent lesions of considerable standing, may be treated less rigidly pending further clinical study. The younger the person, the more labile the lesion is likely to be and the greater the need for prolonged rest. The behavior of symptoms, repeated estimation of the blood sedimentation rate and of the white cell formula, and, above all, repeated roentgenographic examinations, at first every week or two, are the most reliable guides. Consideration of the potential hazard of the lesion, as already discussed, and of the desirability of permanent recovery with the least sacrifice of function often takes precedence and dictates continuation of rest in bed well beyond the time when symptoms have subsided and the hematologic picture is normal. From six to twelve months of sanatorium care is advantageous. Most patients can then gradually resume activities, but a definite limitation of these for another year is usually necessary. Collapse or rest of the lung by pneumothorax or temporary paralysis of the diaphragm may give the necessary lift to the patient who, on rest treatment alone, does not show definite and steady favorable progress. Since these measures occasionally are attended by hazards—some great and some small—there should be a specific and positive reason for using them. They are not necessary for the satisfactory clinical cure of most early infiltrations, and, with the exception stated there is no convincing evidence that

they shorten the desired time of treatment. My experience does not lend support to the view that in these cases pneumothorax can be considered a complete substitute for rest treatment. Few, if any, young people are able under any kind of treatment to continue work without serious jeopardy to their chances of lasting recovery. The apparent economic saving too often turns out ultimately to be a loss.

RESULTS OF TREATMENT

Statistics relating to the results of treatment of early pulmonary lesions are mingled with those concerning lesions which are small but not very early. Furthermore, the failure of patients to report for diagnosis during the first stages of development of the infiltration and the hesitancy of physicians to advise treatment when they do report help to account for the relative scarcity of cases in sanatoriums. I can speak of an experience with more than 100 cases in which the lesions were actually early, since previous roentgenograms showed no disease, they occurred in young people, and observation was possible from one to ten years afterward. This is supplemented by consideration of many hundreds of other cases of rather recent origin in which the duration and course of the disease was reasonably clear though not always verifiable. The experience is not adequate for statistical presentation and I give only a considered judgment, based more on an intensive study of individual cases than on groups. Thus far, most of the untreated cases have progressed into advanced disease. Patients treated promptly and with bed rest at the start have recovered without progression of the lesion in about 90 per cent of the instances. In most of the others, advancement or relapse, if any, has been promptly detected and usually controlled by artificial pneumothorax. Considering permanence of recovery, preservation of pulmonary function and working ability after treatment, the experience has been much superior to any other plan attempted. In the Bellevue School of Nursing the record for the past six and one-half years, during which the ideal plan has been in force, is as follows. All tuberculosis appearing in student nurses has been discovered early, usually in the form of the early infiltration. Progression or relapse of the lesion in spite of rest treatment has occurred in less than 5 per cent of the cases. All who have completed treatment are able to work, and there have been no deaths from tuberculosis. The experience can be said to approximate closely the results of treatment of minimal lesions reported by Brown⁴ from the Trudeau Sanatorium, despite the distinction between minimal lesions and early lesions previously mentioned.

SUMMARY

1 The early lesion of clinical pulmonary tuberculosis is usually a small patch of tuberculous bronchopneumonia in one lung. It appears most often in the ages between adolescence and the late twenties.

2 The early lesion is not often diagnosed except in periodic health examinations or case finding surveys. As a result, most cases are advanced when treatment is instituted. This can be changed.

3 The prevailing tendency of the early lesion in young people is to caseate at its center, excavate and spread. The transition to extensive bilateral pulmonary disease may be a matter of a few weeks, a few months or many years.

⁴ Brown, Lawason. The Present Status of the Treatment of Pulmonary Tuberculosis. *Ann. Int. Med.* 10: 147-155 (Aug.) 1936.

4 Most symptomatic, cavernous, advanced, disabling and fatal tuberculosis originates from the early infiltration

5 Rigid and prompt treatment of the early infiltration, as it appears especially in young people, with a preliminary period of from two to four months' bed rest has proved to be the most effective in terms of lasting recovery and avoidance of advanced relapsing disease

THE DIAGNOSIS AND MANAGEMENT OF LATENT, SUSPECTED AND EARLY CLINICAL TUBERCULOSIS

H W HETHERINGTON, M D

PHILADELPHIA

Methods of tuberculosis control, in large part dependent on the ability to recognize latent and early clinical tuberculosis, have been modified greatly by a better understanding of the epidemiology of the disease and by new and more accurate diagnostic aids. Use of the terms consumption and phthisis to designate pulmonary tuberculosis is very suggestive of the advanced stage in which the disease was generally diagnosed three or four decades ago. The differentiation from other chronic respiratory diseases was not made until marked deterioration of health with emaciation, weakness and dyspnea had occurred, while the hopeless outlook and the stigma attached to the disease made the physician hesitate to make the diagnosis so long as any excuse existed for failure to make it.

Since that time educational campaigns by public health agencies have resulted in recognition of tuberculosis as a contagious disease which can frequently be controlled in the individual case by suitable treatment and can be prevented from spreading to others by isolation or prophylactic care. Examination of the sputum has gradually been accepted as a valuable diagnostic aid. The possible significance of unexplained loss of weight, fatigue, persistent cough, hoarseness, indigestion, hemoptysis and pleurisy with effusion has been repeatedly emphasized and careful physical examination of individuals exhibiting these symptoms has frequently resulted in the diagnosis of tuberculosis at a relatively early stage in its clinical course.

The importance of the diagnosis of pulmonary tuberculosis through history, symptoms and physical signs cannot be overestimated, but unfortunately symptoms sufficiently severe to cause concern often lag far behind the anatomic involvement, so that the majority of patients present moderately or far advanced disease when they first seek medical attention. Physical examination also, even in the hands of skilled examiners, not infrequently fails to demonstrate extensive tuberculous lesions.

Modern methods of tuberculosis case finding employing the tuberculin test and x-ray examination have modified our conception of early diagnosis and have presented the general practitioner with a new problem, namely, the management of apparently healthy persons who present evidence of tuberculous lesions on x-ray examination. These cases are discovered in one of two ways, either through examination of contacts of known tuberculous patients or in tuberculosis surveys of

groups of apparently healthy persons such as high school and college students, pupil nurses and industrial employees. Occasionally cases are found by accident when x-ray examination is made with some other purpose in mind than the discovery of a tuberculous lesion.

The importance of the contact method of tuberculosis case finding is recognized by agencies primarily interested in tuberculosis control. The prophylactic care of contacts should also be the concern of every physician who is treating a patient with pulmonary tuberculosis.

The examination of contacts to discover those who may have been infected by the patient should include the tuberculin test and x-ray examination, since it is asymptomatic or early clinical disease that is being sought. In apparently healthy individuals a negative tuberculin reaction indicates that infection has not occurred, and from a practical standpoint further examination, though desirable, is not necessary to exclude tuberculosis. X-ray examination of all contacts or at least of contacts giving a positive reaction to tuberculin should be made whenever possible. In this way lesions can be discovered before they have caused ill health at a time when they can be most readily controlled.

If x-ray films are too expensive and cannot be obtained free or at a nominal cost, or if for any other reason reliable x-ray reports cannot be obtained, the physician should not relinquish his efforts to determine the results of infection of the contacts. Fluoroscopy, if available, affords an inexpensive diagnostic aid. Recent improvement in fluoroscopic screens has increased greatly the accuracy of this type of x-ray examination. Although inferior to x-ray films, the fluoroscope will reveal the more extensive and therefore probably the more significant pulmonary lesions.

In the absence of these facilities, careful physical examination must be relied on for the discovery of lesions in their early clinical stage. Influenza, colds in the chest or unexplained febrile attacks should be regarded with suspicion and should keep the examiner on guard. Sputum, if present, should be repeatedly examined. Fatigue, loss of weight and other symptoms suggesting tuberculosis require careful observation or even prophylactic treatment.

It is in order to point out that examinations should be repeated at frequent intervals as long as contact exists. When contact is with sputum positive tuberculosis, the interval between examinations should be three months or less. If sputum is not positive, from three to six months is an appropriate interval. The first appearance of a lesion in the x-ray film may occur months after contact with the presumable source of the disease has ceased, and the lesion, when present, may progress so slowly that no symptoms occur for a further indefinite period. For this reason, periodic examinations should continue after contact is finally broken. If x-ray examination is available, two years of observation is sufficient, but if physical examination must be relied on, periodic examinations should be made for at least five years. The importance of periodic examinations requires emphasis because not infrequently contacts are examined only once. If the expense involved prohibits the making of periodic examinations as frequently as has been suggested, they should be made less often rather than stopped completely.

The survey method of case finding consists of the application of the tuberculin test and x-ray examination to groups of apparently healthy individuals in order to discover those presenting asymptomatic tuber-

culous lesions. Students in high schools and colleges are usually chosen for this type of case finding because they are readily available and the incidence of significant lesions is sufficiently high to justify the effort. This is a phase of the tuberculosis control program that is becoming more and more widely employed and in which the family physician should play an important part. A questionnaire sent to twenty-five of the largest cities in the United States in November 1936 revealed that nineteen had some plan for the control of tuberculosis in high school pupils already in operation while in several others plans were contemplated or larger plans were in effect, including high school pupils but not especially applicable to them.

In most tuberculosis surveys the observations are reported to the family physician or to the parent with the advice that he consult the family physician about the report. The reporting of positive tuberculin reactions without x-ray examination often results in needless worry to parents and it is doubtful whether surveys employing the tuberculin test are justified unless provision is made for continuation of the examination. The positive tuberculin reaction indicates tuberculous infection, but x-ray examination is necessary to determine whether or not the infection has resulted in a significant lesion. When a tuberculous infiltration is reported, the tendency on the part of the physician is to reassure the worried patient or his agitated parents and in some instances, unfortunately, the reassurance takes the form of denying either the existence of the lesion or its significance. This opinion is usually given after a physical examination which fails to reveal an abnormality. It must be accepted as a fact that apparently healthy persons may have potentially serious tuberculous disease and that many of those who develop tuberculosis have been strong and robust before the onset of symptoms at a time when x-ray examination would have revealed an active tuberculous lesion. The failure of the physician to recognize the limitations of physical examination and the value of x-ray examination is harmful both to himself and to the tuberculosis case finding program.

In determining the proper advice to give to a patient with latent or early clinical tuberculosis, the family history, the age of the patient, his physical condition and his social status should be considered. Since tuberculosis is a contagious disease transmitted chiefly through contact in the household, the family physician is the person who is best fitted to assume the responsibility for the management of the patient. When patients have tuberculous lesions without symptoms or physical signs, x-ray examination, as already pointed out, must be relied on as a guide to treatment and the physician should understand the type and significance of the lesion with which he is dealing.

The susceptibility to disease and the type of tuberculous lesion that most commonly occurs vary with age. In infancy symptoms and physical signs on which a diagnosis of tuberculosis may be based do not occur until the disease is far advanced or until one of the severe and usually fatal forms of dissemination, such as tuberculous meningitis or miliary tuberculosis, has set in. For this reason the tuberculin test is of special importance in apparently healthy infants who have been in contact with sputum positive tuberculosis. If the tuberculin test is positive x-ray examination should follow, and if a lesion is found, isolation in a hospital is indicated. When the contact is broken and the child has been placed under favorable conditions the prognosis is not hopeless unless the disease is already far

advanced. Even at this age, pneumothorax treatment in unilateral or predominantly unilateral cases may be employed. The lesion found at this age is usually a tuberculous bronchopneumonia or tuberculous pneumonia in the form of consolidation of one or more lobes or parts of one or more lobes. The lymph nodes at the root of the lung are usually enlarged and caseous.

Between the ages of 2 and 12 years the typical lesion found by x-ray examination is the calcified pulmonary nodule with associated calcified focus in the tracheobronchial lymph nodes. Calcification of tracheobronchial lymph nodes recognizable in chest films is not progressive and does not cause ill health but indicates severe exposure to tuberculosis during childhood, which exposure may be continued into adolescence, resulting in the development of a lesion of adult type. Again a second exposure to tuberculosis from a new source of contagion is more likely with these children, since tuberculosis is characteristically a household disease. All members of the households of children exhibiting tracheobronchial calcification should be examined in an effort to locate the source of contagion and other individuals who may have been infected from it.

Calcification may be regarded as evidence of healing, and it is only when calcification has set in that tuberculosis of the tracheobronchial lymph nodes is ordinarily diagnosed. The presence of a calcified focus in the nodes, while leading to a diagnosis of tuberculosis, indicates a condition that is less threatening to health than the caseous focus that preceded it.

Because they do not differ in density from normal structures at the root of the lung, caseous foci in the tracheobronchial lymph nodes, unless very large, cannot be diagnosed and are disregarded. Occasionally the caseous lesion is so large that the nodes encroach on the lung field and in the x-ray film cast a shadow that extends beyond the normal hilus shadow. Here the lesion is discovered at a time when there is no evidence of healing and the possibility of progressive tuberculosis is greatest. The condition must be differentiated from other causes of lymph node enlargement. A history of contact with tuberculosis and a positive tuberculin reaction are suggestive of tuberculosis but do not exclude it by their absence. A complete blood count is indicated as well as examination for enlarged spleen and lymph nodes in other areas. The prognosis in this type of tuberculosis is good in white children if contact is broken. The nodes decrease in size, and calcification may occur.

In the age group under discussion, nonapical pulmonary infiltrations due to tuberculosis of childhood type also occur. The majority do not progress into clinical disease but largely clear, leaving only a few strands in the x-ray film. Lesions of this type that progress must be differentiated from chronic nontuberculous pulmonary disease. The nontuberculous lesion is almost always basal, is often bilateral and is usually accompanied by numerous medium and coarse moist rales. A history of pneumonia, particularly if recurrent, of frequent colds with long continued cough or the presence of infected adenoids or infected accessory sinuses is common, while with severe lesions large quantities of sputum may be expectorated. When the disease is of several years' duration the symptoms are usually much more marked in the winter and slight or absent in the summer. X-ray examination shows that the nontuberculous lesion is most intense near the borders of the heart, which are blurred and just above the diaphragm, the shadow of which is usually irregularly peaked and blurred near the spine. The tuber-

culous lesion can usually be suspected by a history of contact. The tuberculin reaction is positive. Physical signs, including râles, are not marked. Until late in the disease x-ray examination shows that the lesion is usually unilateral or predominantly unilateral and is frequently situated anteriorly, often in the right middle lobe. Severe symptoms and positive sputum do not occur until the disease is far advanced.

Tuberculosis is sometimes suspected in children of elementary school age owing to the presence of underweight and fever. It is sometimes forgotten that the temperature in children is about 1 degree F higher than in adults and may reach 100 F or more without any detectable cause. Underweight has been shown by a number of studies to occur with about equal frequency in tuberculin negative and tuberculin positive children. It should not be considered as a symptom of tuberculosis unless a significant tuberculous lesion can be demonstrated.

Adult type tuberculosis is the chief cause of death between 15 and 45 years of age. The adult type of lesion rarely occurs before puberty but it is found during adolescence with increasing frequency as age advances. For this reason special attention should be given to adolescents and young adults who are in contact with pulmonary tuberculosis. Surveys indicate that apical infiltrations are demonstrable by x-ray examination in about 1 per cent of tuberculin positive boys and 2 per cent of tuberculin positive girls of high school age. The lesion may be present for months or years, as shown by x-ray examination, before it causes symptoms and physical signs. In many instances the lesion becomes scarred and inactive without treatment and without ever having been clinically manifest.

X-ray examination is necessary to determine the site, extent and characteristics of a latent apical infiltration. The tuberculin reaction is positive with few if any exceptions. With more extensive lesions, abnormal physical signs may be detected. Diminished expansion and diminished resonance on the affected side are the earliest physical signs. Crepitant and subcrepitant râles at one or both apices heard on breathing and increased after cough, or heard only after cough constitute the most reliable physical sign. The physical changes are complicated by anatomic differences in the two apices. On the right, owing to the smaller apex and the position of the trachea resonance is diminished, the breath sounds tend to be bronchovesicular and the voice sounds are louder than on the left. For these reasons tuberculous infiltration is often suspected at the right apex. Mild degrees of scoliosis and changes in the position of the subject, particularly in children, also give slight variations in physical signs. It must be recognized that unmistakable physical signs are rarely present in the early lesion, so that slight but persistent abnormal changes should be regarded with grave suspicion.

Very careful attention should be given to the symptoms of adolescents and young adults who are in contact with tuberculosis or who are known to have apical infiltration. So-called grip or influenza, pain in the chest, hemorrhage, cough or any other local or general symptom may indicate the onset of clinical tuberculosis.

The management of latent and early clinical tuberculosis should follow well recognized principles. One of the most important considerations is the prevention of further infection.

If the source of disease is not known, every effort should be made to find it. Examination of all members of the household or others with whom the patient has been in contact should be made. Owing to the

chronic nature of tuberculosis, the original infection may have occurred months or years before the lesion is discovered. On the other hand, the source of contagion may be an unrecognized case of tuberculosis, with which the tuberculous patient is still in contact.

If the origin of disease is known, isolation of the sputum positive case in an institution or removal from the household of the contact with latent or early clinical disease is recommended. If this is not feasible, well known prophylactic measures with regard to cough, to disposal of sputum, to care of dishes and linen and to personal conduct should be observed by all concerned. The physician should inform the patient and family about the danger of contagion or provide written instructions, which are often very helpful.

The physician who is caring for persons in contact with tuberculosis, whether or not they have a tuberculous lesion, should safeguard their health by advice calculated to promote proper hygienic habits. It is reasonable to suppose that attention to these precautions will often prevent the development of a significant lesion.

In addition to periodic examinations for contacts, patients without known contact who exhibit asymptomatic lesions should be kept under observation until it is certain that the disease is not progressive. The type and extent of the lesion are important factors in deciding the frequency with which reexaminations should be made. If the lesion when first seen is of slight extent and its appearance suggests that it has already undergone retrogressive changes, that is, calcification or scarring indicated by a strandlike appearance in the x-ray film, yearly examinations, in the absence of contact, are sufficient. Infiltrations that are not strandlike require examinations at much more frequent intervals, probably every three months, until they undergo favorable changes. In all instances examinations should be continued until the infiltration has a strandlike appearance that does not change during a period of at least three years.

In patients with latent and early clinical tuberculosis the type, extent and clinical manifestations of the lesion determine the treatment that is necessary to control the disease. Rest is the principal factor in treatment, and in many instances partial or complete restriction of activities is indicated.

In a large group, however, in addition to periodic examinations and prevention of continued infection, nothing more is indicated than an ordinary routine including the rest, exercise, nourishment and hygienic habits calculated to promote good health in normal persons. Continued observation of this type without additional restriction of activities is indicated for tuberculous contacts with no demonstrable tuberculous lesion, for preadolescent children with calcified childhood type lesions or strandlike nonapical infiltrations, and for adults with asymptomatic apical lesions, strandlike in the x-ray film.

Partial restriction of activities is indicated for patients with asymptomatic lesions that show no evidence of healing. The modified regimen for these patients includes from ten to twelve hours in bed each night, with a rest hour in the afternoon if possible and extra rest on Sundays and holidays. Strenuous work and exercise are forbidden as well as exertion to the point of fatigue. Three good meals daily should be taken, with extra nourishment if underweight is present.

The patients put on this routine include children with uncalcified lesions of the tracheobronchial lymph nodes demonstrable in x-ray films or nonapical infiltra-

tions that are not strandlike on x-ray examination and adolescent children with apical infiltrations. In the latter, the lesion which has occurred recently should not be regarded as inactive and an altered regimen is indicated, no matter how trivial it may appear to be. Apical infiltration in young adults, unless slight in extent and strandlike in appearance on x-ray examination, also makes an altered regimen desirable.

Patients with more advanced lesions should take sanatorium treatment or its equivalent in bed rest at home. In some instances collapse therapy is indicated in addition. All patients with tuberculosis with symptoms or physical signs should have the advantage of sanatorium treatment regardless of the extent of the lesion or the character of the symptoms. In addition, patients with latent disease whose lesions progress under observation or under an altered regimen are equally in need of sanatorium treatment.

The final success of the method of tuberculosis control through early diagnosis depends on the application of adequate treatment to the progressive lesion either while it is still asymptomatic or immediately after it becomes clinical. The chief emphasis of recent educational campaigns has been placed on early diagnosis. Both the medical profession and the public now require education in the need for early treatment of tuberculosis when there has been slight or no impairment of health.

Henry Phipps Institute of the University of Pennsylvania

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. AMBERSON AND HETHERINGTON

DR. BRUCE H. DOUGLAS, Detroit. Dr. Amberson has said that a person past 30 is not likely to develop serious tuberculosis unless he has acquired a definite lesion before that age. While this is quite true and is well supported by the experience among the nurses which he has reported and is further supported by the work of Fellows, still there is the danger that some of us may fall into a sense of false security and forget that this is a qualified statement subject to definite exceptions. Recently a man aged 62, who had had repeated negative chest films, came to the hospital with acute tuberculosis and died within six weeks. Further this line of reasoning is apt to result in programs like the following. Certain communities are examining school teachers regularly, all positive reactors to tuberculin being roentgenographed every year. If nothing is found by the age of 25 the examinations are discontinued on the basis that serious tuberculosis is not likely to appear after that age if the patient has a clear chest up to that time. Dr. Amberson of course would say 30 years, but even then I am sure he agrees that there are some who will develop disease even after that age. I agree that treatment of these early lesions is imperative. These patients need all the bed rest that Dr. Amberson has outlined as necessary. However in our service rather than just assigning these patients to bed rest alone it is felt that additional valuable rest for the lung can be obtained by the use of a temporary phrenic paralysis. This procedure does not interfere with good visualization of the lesion and yet adds a definite rest factor. If after a month or more observation on the program of bed rest with a phrenic crushing the disease should show progress to more serious proportions, pneumothorax should be employed. The seriousness of these early lesions cannot be too greatly stressed.

DR. CHARLES H. COCKE, Asheville, N. C. One of the outstanding epidemiologic triumphs of medicine today is the gratifying drop in the death rate from tuberculosis. Honestly, however, compels the admission of the facts (1) that modern medicine is not altogether responsible for this drop and (2) that the morbidity of the disease has not shown a similar loss and the further fact that in certain age groups notably women from 15 to 30 years old tuberculosis is still the greatest single cause of death. The explanation of this paradox I feel resides in our lack of knowledge of the exact incidence and the degree

of infection in the second, third and possibly fourth decades of life. Much has been learned of the incidence of infection in school and college groups, student nurses and such related controllable groups but so far no one has evolved a solution at once economically possible and scientifically sound for application of our known methods of detection of tuberculosis to the entire population. When health preserved becomes as precious as health lost and the same efforts and funds are available to attain this end, perhaps we shall be somewhere near, or at least nearer, the solution of the problem of tuberculosis. I am delighted to commend Dr. Amberson's stand for the prolonged treatment of the early lesion, as well as his method of treatment. In the present wave of enthusiasm for compression and surgical procedures in the treatment of tuberculosis it is well to reiterate that surgical intervention does not cure tuberculosis any more than a splint cures a fracture, that all such measures are but means to an end of assisting nature to do what we as yet have not had the wit to accomplish by pharmacologic, chemical or serologic agents—cure tuberculosis. The only known specific, as has been preached for years, is rest, and yet this means many things to many minds. One of the greatest paradoxes of the disease is the disparity between symptoms, physical observations, and roentgen appearances. The solution can be reached I feel only by an evaluation of a fourfold approach to the problem: historical (which cannot be too greatly emphasized), physical (which may be fruitless but frequently lends suspicion in some minutiae), roentgenologic (which is still our mainstay and most valuable help), and laboratory studies (which aid greatly in evaluation of the process discovered by the other measures).

DR. FRANCIS M. POTTENGER, Monrovia, Calif. It is unfortunate, in dealing with tuberculosis, that health boards and specialists devise plans for examination and diagnosis which fail to give the general profession an intimate part in the program. Medical men in general should take the same interest in tuberculosis that they do in diseases of the heart, kidney and blood, for tuberculosis is a part of general medicine. There is neither mystery nor magic in its diagnosis. Any well trained physician can carry out the three simple measures of greatest value in diagnosis: (1) take a careful history, (2) have the sputum examined and (3) have a roentgenogram of the chest made. By making early diagnoses and at least understanding the principles of treatment, they can render as great a service to the tuberculous patients as to those suffering from other diseases. The reason specialists are dealing so constantly with far advanced tuberculosis is the fact that general medical men have largely excluded tuberculosis from their practice and failed to accept responsibility for it. They can and must accept the responsibility at least for diagnosis. We must not let the fact that specialists have devised means whereby they are able to produce healing in far advanced cases militate against early treatment. Far advanced patients are more or less handicapped for the future, and their treatment is unnecessarily expensive in both time and money. The only patient who can get well regularly and be fully competent is the one with the early or limited lesion. Dr. Amberson's point of view is sane. In private practice I make it a rule not to use any mechanical measure which carries with it the possibility of injury to the patient's respiratory mechanism unless I deem it necessary to his cure. In my relationship to indigent patients, however, I accept the necessity of interfering more frequently, because of the limited facilities for treatment at hand. Statistical proof is necessary however, before one can be certain that it is the best practice. Nearly all patients with limited infiltration in the lung can be restored to health by physiologic treatment alone. An important factor in determining the character of treatment to be employed, as well as the permanence of results, is the environment in which patients live, both during and after treatment. The case is very different for those who go back to a bad environment as compared with those whose surroundings are favorable. Those who treat tuberculosis are obliged unfortunately to handle the material that comes to them regardless of the extent of the disease, with the facilities with which they are provided, whether it is best clinical practice or not. There is danger, however, that results obtained under unfavorable conditions will influence one to advocate the same method under all conditions.

DR S A SAVITZ, Philadelphia It cannot be sufficiently emphasized that early diagnosis of tuberculosis at the present time is the most important procedure in controlling the disease. Great strides have been made in the treatment of advanced cases. Artificial pneumothorax, thoracoplasty and phrenicotomy are in a great measure responsible for the reduction of the mortality. Just as soon as the diagnosis is made at the very onset of the disease, the incidence and mortality will be reduced tremendously. It is strange that many of our present day trained physicians wait for pronounced symptoms, such as fever, cough and expectoration, even to suspect pulmonary tuberculosis. What is wrong? They are getting the best training in physical and clinical diagnosis from the freshman to the senior years, they are taught to correlate and evaluate symptoms and physical signs, they serve an internship in hospitals and attain practical experience to make them able men. Nevertheless many fail to diagnose tuberculosis at its early stage. I believe the principal reason is carelessness. At the Philadelphia General Hospital, where we house about 400 tuberculous patients, over 50 per cent on admission give a history that they have been treated for colds or something else not related to tuberculosis. I do not think that more headway will be made in the future until specialists properly instruct the general practitioner to be more careful and also instruct people in general to take better care of themselves. Periodic health examinations with an effort to diagnose tuberculosis in its incipient stage and our present day knowledge of thoracic surgery will, in my opinion, reduce the mortality and incidence of the disease to a minimum in the next ten years.

DR SAMUEL FRIEDMAN, New York Some patients with early or moderately advanced tuberculosis are not distressed by a cough sufficiently to call it to the attention of the doctor. When asked about a cough they may even answer "No." Particularly is the absence of a complaint about a cough true if the patient is suffering also from an associated painful disease, such as gastric or duodenal ulcer or renal or cardiac pains, the symptoms of which are so distressing as to mask the little annoyance of a slight cough or expectoration. Such early uncomplicated cases of tuberculosis are frequently overlooked or the patients are treated for bronchitis, and if this is associated with another distressing disease are treated only for the symptoms of the annoying coexisting disease. It is necessary never to ignore a slight or moderate persistent cough or expectoration. It is most advisable at times to stress the question X-ray and sputum analysis and a tuberculin test when in the slightest of doubt will save many a regret. On the other hand, it must also be borne in mind that there are some diseases the symptoms of which simulate clinically those of tuberculosis. I refer particularly to subterminal hyperthyroids. The patients may have fever, anemia, exhaustion, loss of weight or rapid pulse and may even have a cough because of the pressure of an enlarged thyroid against the bronchus. I have known several subterminal hyperthyroids and one normally located only slightly enlarged but hyperactive thyroid to be treated for tuberculosis over a long period. During the past three years I invited some of the best physicians and surgeons of New York and elsewhere to give lectures to groups of my patients on the subjects in which they specialized. The patients were much impressed with these talks, sitting eagerly through them for three or four hours at a time. Dr Baehr and some of the other speakers suggested that it would be a good idea to have this method of bringing these talks to the public generally adopted by the members of our profession. The patients demonstrated that they are really eager to learn. It is our task to guide them and teach them the laws of life and the danger signals of disease to keep them well and to help them recognize and treat their ailments early. I hope that in the near future every physician will realize the value of such educational talks to his own flock.

DR ESMOND R. I. The papers deal essentially with the underlying pathogenesis of tuberculosis, the early arrest and cure. The treatment is essentially constructive. The early cellular collections even in solid rather than liquid

in its location and that there is little fluid movement in the bronchi and relatively little absorption of products of either of tissue or of bacilli. Under such circumstances the symptoms result, and physical signs dependent on exudate liquefied tissue in the air passages are not present. In this stage is not sick, nor would physical examination in some routine way be likely to bring his trouble to light. However, he is in grave danger. His disease process is analogous to an unfired charge of explosive powder. Should the tuberculous tissue break down, all the elements are at hand for rapid spread. Tubercle bacilli are numerous in softening caseous tissue, and the bronchial channels permit immediate and extensive spread to healthy parts of the lung. With this spread of highly infectious material come cough, fever and the chain of clinical events characteristic of tuberculosis. The onset of the disease is naturally dated by the patient with the onset of the symptoms, yet the true onset antedated this symptomatic outburst by months or even years. Since the task of controlling the first or relatively symptomless stage of tuberculosis is far easier than controlling spread and repair of damage after softening and cavity formation have set in, we must have recourse to methods that detect tuberculosis in its earliest or symptomless stage.

THE ORAL ADMINISTRATION OF PROSTIGMIN IN THE TREATMENT OF MYASTHENIA GRAVIS

HENRY R. VIETS, M.D.
ROGER S. MITCHELL, M.D.
AND
ROBERT S. SCHWAB, M.D.
BOSTON

Shortly after the introduction in 1934 of parenterally administered prostigmin in the treatment of myasthenia gravis, prostigmin given orally was also shown to be effective in ameliorating the symptoms of this disease. Administering doses of 30 mg by mouth three times a day, Everts¹ had encouraging results in two patients after two or three months of treatment. No untoward symptoms were noted. Only a few other reports have appeared: those of Schneider,² Laurent and Walker³ and Smith⁴ and a report from our clinic by Mitchell.⁵

It was soon found that 30 mg of prostigmin by mouth was about as effective as 0.5 mg given subcutaneously or intramuscularly. The ordinary dose by mouth therefore was from three to six tablets, of 15 mg each, a day. Laurent and Walker,³ beginning about June 1935, soon ran out of supplies of prostigmin to be given orally and had to substitute a similar drug known as Substance 36. About 50 mg of this drug by mouth gave an effect equal to that produced by 1 mg of parenterally administered prostigmin. In no case did they note unpleasant symptoms or aggravation of the myasthenic condition of their patients. Smith⁴ reported that in one case prostigmin was used orally "with even greater benefit than by injection." Mitchell⁵ observed nine patients, his results are incorporated in the present paper. No severe reactions were noted by any of the workers when prostigmin was

given orally to patients with myasthenia gravis Goodman and Bruckner,⁶ however, noted severe symptoms due to poisoning when one of them (Goodman), a man in good health, took 45 mg of prostigmin orally in a single dose. There were vigorous tonic contractions of the muscles of the skeletal and visceral systems, presumably due to the inhibition of the normal esterase at the motor end-plate and the prolonged stimulation by acetylcholine, as noted by McGeorge.⁷ Goodman and Bruckner felt that, because of their experience, prostigmin should not be used for the present by mouth. The warning, as far as our observations and those of others⁸ are concerned, was unnecessary.

REPORT OF CASES

The eighteen patients whose brief case histories are given hereafter have been taking prostigmin by mouth continuously for from one to fourteen months. Some were known to us years ago, others have come to the clinic only recently. The former patients were treated in the past with aminoacetic acid, ephedrine and other drugs, often with considerable effectiveness. Since the advent of the prostigmin test of Viets and Schwab,⁹ the number of patients entering the clinic has greatly increased over former years, fifteen having been added from June 1936 to July 1937. This report covers the period from May 1936, when prostigmin¹⁰ was first administered orally by us, to July 1937.

CASE 1—J K K (Massachusetts General Hospital), an unemployed man, aged 70, first noticed ptosis of his right eye and diplopia in January 1935. A year later, dysphagia, regurgitation of liquids through his nose and ptosis of the left eyelid occurred, and chewing movements became weak. On a number of occasions he had to be fed by tube, and his condition was considered critical. In prostigmin tests in May and June 1936 he scored 32 and 37 points on the old scale.^{9a} Benzadrine and aminoacetic acid were tried without effect, ephedrine gave slight improvement. Prostigmin, given orally since May 1936, has effected a good and continuous remission. Dysphagia and dysarthria are largely controlled, ptosis and diplopia, partly so. The present maintenance dose is 15 mg of prostigmin taken nine times a day, supplemented with three-eighths grain (0.024 Gm) of ephedrine three times a day and from 10 to 15 drops of tincture of belladonna three times a day.

CASE 2—R S H (Massachusetts General Hospital), a salesman, aged 49, first noticed general weakness in the fall of 1935. About January 1936 he could hold up his head for only short intervals and weakness of his arms and legs forced him to give up an office position. Dysphagia and dysarthria, as well as diplopia, came on rapidly, and he entered the hospital in March 1936. His score in the prostigmin test was 68 points. Ephedrine and benzadrine gave partial relief. Oral administration of prostigmin was started in May 1936. The patient has regained some weight, and the dysphagia and dysarthria have in large part disappeared, but the weakness of the neck continues, necessitating support by a Thomas collar. The patient, although not able to work, is greatly improved, having progressed from a critical condition to one in which life is tolerable. He is able to come to the hospital at frequent intervals. His present maintenance dose is as follows: prostigmin, 15 mg nine times a day, ephedrine, three eighths grain (0.024 Gm) three times a day, and tincture of belladonna, 5 drops for each 15 mg of prostigmin.

CASE 3—M G (Massachusetts General Hospital), a woman, aged 76, noticed bilateral ptosis, dysphagia and weakness in chewing and in using her hand about April 1936. Her symptoms were worse after emotional stress and particularly late in the day. The result of a prostigmin test in June 1936 was reported as 70 points. Oral administration of prostigmin was begun at this time, and the patient reported by letter that she was "much better" in July 1937. Her maintenance dose has not been definitely determined.

CASE 4—M J M (Massachusetts General Hospital), a truckman, aged 62, first noticed ptosis in February 1934, followed by occasional attacks of diplopia in the next year. Dysphagia and dysarthria, coming on in the spring of 1935, led him to enter the hospital in July 1936. The score of his prostigmin test was 58 points. Unable to speak or swallow, he was first treated by intramuscular administration of prostigmin. Within an hour he could take 15 mg of prostigmin by mouth. During the next four months he improved only slightly with an irregular consumption of six tablets a day, with belladonna. Marked dysphagia and dyspnea developed, and he entered the hospital in October 1936, moribund. He was quickly revived again by intramuscular injection of prostigmin, and his oral dose of prostigmin was increased to eight tablets a day, with potassium chloride. In January 1937 his condition was good, he drove his automobile and had gained 25 pounds (11 Kg).

In the middle of February 1937 the patient had a cold and shortly afterward some difficulty in swallowing his prostigmin tablets. Three or four days after the onset his condition became decidedly worse. He entered the hospital February 22, showing marked dysphagia and dyspnea. Prostigmin, 45 mg injected intramuscularly, gave him considerable relief, but the effect of this drug did not continue, and on February 24 he died, showing respiratory embarrassment and elevation of temperature. There were no signs of pneumonia. No postmortem examination was allowed.

CASE 5—J B (Massachusetts General Hospital), an unemployed man, aged 20, was first seen in May 1932 with generalized muscular weakness of ten months' duration, associated with dyspnea, dysphagia and diplopia. He took ephedrine from 1932 to 1935, with moderate effect. Aminoacetic acid was used in 1935, with less effect than ephedrine. His condition became much worse, over a period of a few months, when he stopped taking both drugs. Injections of prostigmin in April 1935 caused marked improvement, and he continued taking two ampules, intramuscularly, a day until July 1936, when he changed to prostigmin by mouth. In his prostigmin test he scored 47 and 60 points on two occasions. Six tablets of prostigmin, 15 mg each, did not control his symptoms, and it was found that his maintenance dose had to be raised to twelve tablets a day, with three-eighths grain of ephedrine three times a day and 3 drops of tincture of belladonna three times a day. Taking this dose he is able to come to the clinic each month but is not able to work. He has no dysphagia or diplopia.

CASE 6—E H (Massachusetts General Hospital), a housewife, aged 27, had dysarthria, diplopia and dysphagia for four or five months before entering the hospital in March 1932. She responded slightly to ephedrine, and at times all the symptoms except the diplopia were nearly absent. During pregnancy she was much improved. She had a relapse three months after delivery. Seen again in August 1936, she had all her previous symptoms. In her prostigmin test she scored 45 points. Oral administration of prostigmin was begun in August 1936. Her maintenance dose is as follows: prostigmin, 15 mg, ten tablets a day, with tincture of belladonna, from 3 to 5 drops three times a day. Her condition is good.

CASE 7—F J R (Massachusetts General Hospital), a salesman aged 66 had dysarthria in 1932, lasting a week. In 1934 his condition became acute with weakness of the muscles of the neck, dysphagia, dysarthria, regurgitation of fluid through his nose and diplopia. In November 1934, while in the hospital, he began taking ephedrine and aminoacetic acid, with slight improvement. On four occasions he took physostigmine sulfate without effect. Potassium chloride and prephysin (Chappel) were also tried, the patient grew worse and returned to ephedrine and aminoacetic acid. In his prostigmin test he scored 49 points. In August 1936 he began taking prostigmin by mouth. His maintenance dose in July 1937 was as follows: prostigmin, 15 mg twelve times a day, with atropine sulfate,

3/200 grain (0.3 mg) four times a day. At present he is able to walk, talk and swallow without difficulty. There is no diplopia. His general condition is good, but he could not return to his former occupation.

CASE 8—M T (Dr E M Cole), a woman, aged 53, a bookkeeper, first complained of general weakness and diplopia about January 1936. Her symptoms increased rapidly in July 1936, so that she could not lift her head from the bed. There were dysarthria, dysphagia and ptosis. All her symptoms grew more pronounced toward evening. In her prostigmin test she scored 68 points. Her maintenance dose is 15 mg of prostigmin six times a day and from 5 to 10 drops of tincture of belladonna three times a day.

CASE 9—F G (Dr J B Ayer), a housewife, aged 37, began to have the symptoms of ptosis, diplopia and general muscular weakness in 1923. Dysarthria was an added symptom in 1928. At this time she could not turn over in bed. With ephedrine and aminoacetic acid she improved in 1930. In her prostigmin test in 1936 she scored 52 points. She began taking prostigmin by mouth in August 1936, with better results than with any previous form of medication. Her maintenance dose in July 1937 is from six to eight tablets a day. Her condition, in spite of her long illness, is good.

CASE 10—M H (Massachusetts General Hospital), a woman aged 23, a student, acquired ptosis and diplopia about 1930. A year later the trunk and the extremities were involved. In 1932, during a relapse, she was confined to bed and had difficulty in swallowing. For about five years she has been taking ephedrine, with partial relief. She is worse during her catamenia. In her prostigmin test she scored 35 points. Her maintenance dose at present is prostigmin 15 mg eight times a day, with ephedrine, three-eighths grain, four times a day. She is very well, free from symptoms and able to work.

CASE 11—F E S (Palmer Memorial Hospital), a man aged 59, a physician, first noticed diplopia in 1932. It lasted a month, and no other symptoms appeared until June 1936, when dysphagia developed, followed by dysarthria, ptosis and mental depression. In his prostigmin test he scored 39 points in September 1936. He began taking prostigmin by mouth at that time. His maintenance dose is five or six pills a day and ephedrine, three eighths grain three times a day. Totally incapacitated at the time of admission to the hospital, he is now able to see a limited number of patients and drive his automobile.

CASE 12—J L P (Massachusetts General Hospital) a fireman, aged 52, first noticed ptosis and diplopia in December 1936. His symptoms were worse in the afternoon. There was no dysarthria, no dysphagia and no general weakness. The result of his prostigmin test with the revised score, was 46 points. The administration of prostigmin by mouth was begun in February 1937. His maintenance dose is eight pills a day with atropine sulfate 1/30 grain (0.4 mg) three times a day. He is now able to work.

CASE 13—F D (Massachusetts General Hospital) a mill-worker, aged 50, first noticed ptosis and diplopia in April 1936. He was worse in the afternoon. In his prostigmin test he scored 58 points. He began taking prostigmin by mouth in March 1937, and his maintenance dose in July was nine pills a day, with ephedrine three-eighths grain two times a day.

CASE 14—S J S (Massachusetts General Hospital), a housewife, aged 47, first had ptosis in 1933, with weakness of her neck. In 1936 there was weakness of her arms. Electromyograms and ergogram showed myasthenia gravis. Oral administration of prostigmin was begun in April 1937. Her maintenance dose is eight pills a day. She is moderately improved.

CASE 15—S S (Massachusetts General Hospital) a housewife, aged 62, had ptosis in 1936. It occurred again in the fall of 1937. It was relieved within a few months, and both symptoms were better in the afternoon. The result of her prostigmin test with the revised score was 35 points. Improved. Her maintenance dose is six pills a day.

CASE 16—L P R (Massachusetts General Hospital) a housewife, aged 22, began to have dysphagia in April 1936. General weakness and dysarthria in the afternoon. Ptosis was noted in June 1937. The result of her prostigmin test, with the revised score, was 50 points. Her initial dose was four tablets of prostigmin a day.

CASE 17—M K (Massachusetts General Hospital), a school girl, aged 14, began to have dysarthria, dysphagia and general weakness in the summer of 1935. In her prostigmin test she scored 49 points. Some improvement was noted while she was taking ephedrine. She began taking prostigmin by mouth in July 1937, her initial dose being four pills a day.

CASE 18—N G (Massachusetts General Hospital), a housewife, aged 46, first noticed diplopia in October 1934. Because of her hypertension the condition was thought to be due to cerebral hemorrhage. Ptosis developed in 1935. Her prostigmin test showed myasthenia gravis. Her initial dose of prostigmin was four tablets a day.

In the month of July three additional patients were seen in the clinic. They are doing well on prostigmin taken orally.

COMMENT

Dosage—Prostigmin is supplied in tablets of 15 mg each for oral administration. Our doses have been from four to twelve tablets a day. The initial dose is spaced at four hour intervals, usually four tablets a day. This dose is often too small to maintain muscular efficiency, and it must be increased to from six to twelve tablets in the twenty-four hour period. A maintenance dose, established in two or three weeks,

Ephedrine	2	2

Dosage chart used in case 1

will average from four to nine tablets a day. This dose in thirteen of our cases is as follows: two cases, twelve tablets a day, one case, ten, three cases, nine, three cases, eight, one case, from six to eight, three cases, six. These doses have been maintained with slight variation from two to fourteen months: three cases, fourteen months, one case, thirteen, two cases, eleven, one case, ten, two cases, five, four cases, four, two cases, three.

For patients taking prostigmin by mouth, the spacing of the doses has been of considerable aid in maintaining muscular efficiency during the waking hours. With six tablets a day, the doses are taken at 6 and 9 a.m., 12 noon, and 3, 6 and 9 p.m. The dose may be doubled before meals, at 6 a.m., 12 noon and 6 p.m., making an intake of nine tablets, or 135 mg of prostigmin, a day for an adult. Thus, according to our experience, is the common maintenance dose for a severe case of myasthenia gravis. A few patients require two tablets at each of the six periods or twelve tablets a day. This dose has been taken by two of our patients (cases 5 and 7) for ten or twelve months. Unequal spacing in some cases may give the best results. In view of this fact we use a printed chart showing the hours from 8 a.m. to 10 p.m. in columns, with another column for the night. The drugs used are written in, and the chart is given to the patient, showing the time when the drugs are to be taken.

Effect—Thirty milligrams of prostigmin administered orally is, in most instances, equivalent to 0.5 mg of

prostigmin in a 1 2,000 solution given intramuscularly. The effect, however, is not so prompt and is less likely to be complete. The response comes in about one-half hour, reaches a maximum in one or two hours and wears off in three or four hours. During this period the paretic muscles regain their power in part or in whole. The visceral disturbances are variable. Some patients have none, others complain of considerable abdominal discomfort, diarrhea or a desire to evacuate the bowels. When disagreeable symptoms are induced by prostigmin given orally they may be controlled by tincture of belladonna in doses of from 3 to 15 drops or by atropine sulfate, $\frac{1}{200}$ grain (0.3 mg.) given with the prostigmin. Twelve of our eighteen patients took belladonna or atropine, the dose varying in amount with the abdominal discomfort. The visceral symptoms are often absent when only one tablet of prostigmin is taken at a time.

Patients with severe myasthenia gravis often have great difficulty in getting out of bed in the morning when the effect of the prostigmin taken the night before has worn off. A few patients have been awakened at 1 or 2 a. m. to take one or two tablets. Most of them take two tablets as soon as they wake up, either by themselves or with aid. For those who have difficulty in swallowing early in the morning, prostigmin is now being tried in suppository form. In the most severe cases an ampule of prostigmin should be at hand for emergency injection.

Adjuvant Drugs—In the last year many of the drugs used in the treatment of myasthenia gravis before the days of prostigmin have been experimented with as adjuncts to prostigmin. Those still in use by our patients are potassium chloride, ephedrine and benzedrine. A few patients think potassium chloride valuable in prolonging and "evening out" the effects of prostigmin. The drug, however, is gradually being given up. When three-eighths grain of ephedrine was added to the prostigmin, more than one half of our patients were improved. With it the patients have less abdominal discomfort, and often the amount of prostigmin can be reduced when ephedrine is taken.

CONCLUSIONS

Oral administration of prostigmin may be safely used in the treatment of patients with myasthenia gravis in daily doses of from three to twelve tablets of 15 mg. each. When ingestion of the drug is carefully spaced, patients maintain a reasonable degree of muscular efficiency, certainly better than with any other form of treatment. No ill effects were noted in eighteen patients treated from one to fourteen months. Other drugs may be added to the prostigmin regimen with benefit.

ADDITIONAL NOTE

Since this paper was written during the months of July, August and September, five new cases were added to the clinic.

CASE 19—E. A. (Massachusetts General Hospital), a housewife, aged 21, first noticed dysphagia in 1934, ptosis occurred in 1936. Her prostigmin test score was 32. Beginning with an initial dose of four tablets of prostigmin a day, she is now taking six tablets with symptomatic relief.

CASE 20—E. T. (Massachusetts General Hospital), a school-girl, aged 17, has suffered from ptosis, diplopia and ophthalmoplegia since 1933. Her prostigmin test was scored at 55 points. Under a dosage of four tablets a day with one occasionally in the evening, the patient is partly relieved of her symptoms.

CASE 21—T. E. (Massachusetts General Hospital), a man aged 53, first noticed ptosis and partial ophthalmoplegia in

the spring of 1937. His prostigmin test score was only 16. On four tablets a day there has been well marked improvement.

CASE 22—B. R. (Massachusetts General Hospital), a man, aged 48, first noticed diplopia and ptosis of the left eye eleven months before admission. He complained, however, of weakness in his neck and arms practically all his life. His prostigmin test score was 45. On five tablets a day there has been distinct improvement.

CASE 23—L. B. (Massachusetts General Hospital), a housewife, aged 66, first noticed weakness of her legs two or three years before admission. For about eight months she had had ptosis of both eyelids. Prostigmin given subcutaneously gave prompt relief of the ptosis. A dosage of from three to four tablets a day has resulted in partial symptomatic relief.

During the last three months, attempts have been made to reduce the amount of prostigmin and the adjuvant drugs. In one case the prostigmin was reduced from eight to five tablets a day and in three others a reduction of one or two tablets has been made without ill effects. In practically all the cases, moreover, atropine has been omitted and belladonna reduced to from four to eight drops, three times a day. Only one of our patients is now taking potassium chloride.

THE TREATMENT OF NEPHROSIS IN THE YOUNG CHILD

FREDERIC W. SCHLUTZ, M.D.

AND

JAMES L. COLLIER, M.D.

CHICAGO

The treatment of nephrosis, the chronic renal disorder so peculiarly prevalent in childhood and adolescence and of which the exact etiology is still quite obscure, offers many perplexing problems to the practitioner.

Aside from its chronicity, one of the most disconcerting characteristics is its tendency to alternate remission and severe exacerbation and its reappearance after long periods of apparent cure.

Although considerable progress has been made in the treatment of the condition, no form of therapy is really consistently successful or gives assured relief for the more troublesome symptoms. Outstanding among these and most alarming are the excessive, sometimes huge, losses of protein in the urine and the development of anasarca and ascites to a degree hardly equaled by any other condition affecting the child.

The albuminuria cannot be treated but can be overtreated, much to the harm of the patient when it is made the excuse for excessive limitation of the protein intake. Considerable changes in the protein content of the diet have little or no effect on the daily proteinuria. In this condition there is no need to worry about nitrogen retention in the blood on ordinary or even moderately elevated protein diets.

The edema in the nephrotic child is usually the special object of therapy and relief from it the chief concern. Rest in bed is always absolutely essential. Practically all hydrotherapeutic measures are feeble agents for the relief of edema.

Restriction of salt and fluid intake is of the greatest importance, will always affect the condition favorably and may give temporary or complete relief even though edema favoring factors such as persistent albuminuria

and low plasma proteins may still be present or persist. Common sense and the general state of the patient must guide the rigidity of this restriction.

The fairly well nourished child, even with some edema, is better off than the child made edema free at the expense of gross emaciation. Excessive restriction of water in the young child may effect great hardship and is not without danger from the development of toxic states.

Practically all forms of diuretics, such as the purines, theobromine, the acid-forming diuretics and the mercurials, are entirely or relatively safe because the functional capacity and structure of the kidney are not essentially damaged, but their effect in nearly every instance is quite disappointing and practically never of sustained value.

Thorough removal of focal infections, especially about the upper respiratory tract, a procedure particu-

tional favorable reports appeared subsequently in *6 Hospital Reports* and the *Lancet*.

Osman and many others before him have found that some degree of acidosis is practically the rule in both acute and chronic renal disease. It has been quite definitely established that the accumulation of phosphate is probably the principal factor in the production of this acidosis. Not alone does there seem to be a decrease in the plasma bicarbonate in cases of nephritis, but there seems also to be an increase in alkali tolerance. There seems to be no direct relationship between the degree of acidosis as measured by the plasma bicarbonate and the severity of the symptoms present.

The procedure of high alkali therapy in renal disease is based primarily on some theories expressed by Martin Fischer over a decade ago, who held that the colloidal proteins of the body tissues and cells have the property of imbibing or parting with water with alterations in

Summary of Fourteen Cases of Nephrosis

Case	Sex	Age yrs	Type	Probable Duration	Chief Symptoms	Blood Urea Mg %	Maximum Diuresis Oz per Day	Total Weight Loss Pounds	Effect on Edema	Comment
1	♂	3	Chronic parenchymatous	1 yr	Anasarca ascites		70	10½	Cleared entirely	No edema or albumin well 1 yr later
2	♂	2	Chronic parenchymatous	1 yr	Anasarca ascites			3½	Cleared	No edema or albumin died from summer diarrhea later after recovery
3	♂	3	Acute parenchymatous	1 mo	Extreme anasarca and ascites					Edema and albumin cleared but patient died of pneumococcal peritonitis kidneys at autopsy normal
4	♀	4½	Chronic parenchymatous	6 mos	Anasarca, ascites	67	61	16	Cleared entirely	Edema cleared up but returned and then not controlled died no autopsy
5	♂	2½	Acute parenchymatous	3 mos	Anasarca anuria no ascites				Cleared	Treatment omitted at home readmitted 1 mo later anasarca anuria ascites died
6	♀	4	Chronic parenchymatous	3 mos	Anasarca ascites traces of blood in urine	12				No result from treatment continued to do badly and died no autopsy
7	♀	5	Chronic parenchymatous	2 yrs	Anasarca ascites	32	75		Cleared entirely	Relapsed 6 times in 4 yrs cleared up each time with treatment
8	♀	9	Chronic parenchymatous	11 mos	Anasarca ascites				Cleared	Edema cleared but patient died of pneumococcal peritonitis
9	♂	6	Chronic parenchymatous	6 mos	Extreme anasarca ascites	44	44	11½	Cleared entirely	No further treatment well 1 yr later
10	♂	13½	Chronic mixed symptom	10 yrs	Edema of face legs anasarca ascites	39	87	6	Cleared	No edema for 4 yrs most of albumin cleared blood urea increased lag improved
11	♂	7	Chronic parenchymatous	5 mo	Anasarca ascites	29	60			Remained free from edema for 4 yrs under treatment then died of pneumococcal peritonitis
12	♂	5½	Acute parenchymatous	wk	Anasarca ascites					No result from treatment died from tetany
13	♀	4	Chronic parenchymatous	1 yr	Anasarca		60	9	Cleared entirely	Well
14	♂	7	Chronic parenchymatous	1 yr	Anasarca ascites				Cleared entirely	Edema returned twice and twice cleared up with treatment
Results: Died 10 out of 14										

larly emphasized and championed by our late lamented colleague Marriott and his associates often is truly spectacular in its effect but again it will completely fail in case after case. Our experience with repeated blood transfusions has not been very striking.

Mechanical removal of excessive edema fluid often becomes imperative and will frequently have a very favorable effect on the whole condition and especially the reestablishment of an active diuresis.

All these procedures must be done with great care and under the strictest asepsis. I recall three cases in which a continual siphoning of ascitic fluid from the abdomen for a period of from three to four weeks effected a complete cure. A fourth patient died of pneumococcal peritonitis.

A few years ago, London published some results on the use of alkali in acute and chronic forms of nephritis. He advocated particularly the use of sodium bicarbonate in generalized anasarca and ascites.

the surrounding medium. Any change in the acid base relationships, such as alteration in the reaction of the medium and change from the iso-electric point, results in significant change in cellular water content and its distribution in the body. While the theories of Fischer have been criticized and are still controversial, there are some aspects of them which offer reasonable explanations of this peculiar action and the effect of alkalis in the treatment of some renal disorders.

It is more than probable that many of the biochemical disturbances found in the blood in nephritic patients are determined in part at least by the permeability or physical condition of the membrane of the renal cells. It is probably here that the explanation of the effect of alkalis in chronic renal disease must be sought. It is on the basis of some of these theories and concepts that Osman suggests his procedure. He believes that alkali may be used with advantage in many cases of nephritis under certain circumstances for either their prophylactic or their therapeutic value.

It is important to know the plasma bicarbonate level before treating a case of nephritis with alkalis

Cases of nephritis presenting edema, high albuminuria and low urinary volume are likely to derive the greatest benefit from alkalis given in amounts sufficient to raise the plasma bicarbonate to a normal level and maintain it at that point. In favorable cases a marked diuresis and subsidence of edema will occur when this point is reached. The output of albumin is generally greatly diminished, and it may in time completely disappear.

The acute or chronic parenchymatous or nephrosis type of renal disease with little or no structural impairment of the kidneys offers the most suitable case for this form of treatment. Also, however, it is useful in the treatment of mixed forms in which there is considerable structural damage and oliguria and edema with low plasma bicarbonate level. It is least effective in the chronic interstitial forms with hypertension, although even in these cases it may give some relief for excessive edema if the plasma bicarbonate level can be raised.

While this form of treatment in no way restores a structurally damaged kidney or stays a process operating to that end, one can expect with certain confidence a marked improvement or even complete regression of some of the distressing symptoms of the case, such as excessive edema, oliguria, anuria or excessive proteinuria, provided enough alkali is given to restore the plasma bicarbonate to a normal level and to keep it there.

The treatment often calls for truly heroic doses of alkali and is not altogether without danger. Overdosage must be guarded against by a periodic checking of the plasma bicarbonate. The alkaline salts are given by mouth until the plasma bicarbonate reaches a normal value, or in the absence of untoward symptoms they may be given even beyond this point. Confinement to bed is essential except in the mildest case, and the treatment is best carried out under hospital management.

Except in the presence of oliguria or hematuria, an ordinary mixed diet without restriction of protein or salt can be allowed. No excessive restriction of fluid need be imposed, although care must be taken that the fluid intake does not greatly exceed the fluid output.

The alkalis are given in the form of potassium citrate, potassium bicarbonate, sodium citrate and sodium bicarbonate, generally in equal quantities. Water is added and some flavoring agent, enough to disguise the taste. Syrup of orange or peppermint water and chloroform water are good agents.

The potassium salts are more effective in reducing edema and promoting diuresis than are the sodium salts, but the former are more dangerous on account of possible toxic action on the heart. The sodium salts, though less powerful, have much the same action. If used alone they cause more initial increase of edema than if used in combination with the potassium salts.

All the salts may cause some unfavorable effects, the bicarbonates tend to cause nausea and vomiting and the citrates often produce alarming diarrhea, especially in children. All these difficulties are best overcome by combining the salts as described. In cases of coma, the alkalis may be given by rectum as a 3 per cent solution

of the foregoing mixture. Intravenous therapy with the alkalis has been attempted but is not very successful and is technically difficult. During the treatment the total amount of urine passed in the twenty-four hours must be known, a record of the patient's weight must be kept and the reaction of the urine must be tested on early morning specimens.

The plasma bicarbonate should be estimated before the treatment is started and again at intervals during the treatment, especially if untoward symptoms supervene. For children the initial dose of the four alkalis in equal mixture is from 2 to 3 Gm or 30 to 50 grains three times a day. The following day this amount is given four times a day, or a total of from 8 to 12 Gm or 120 to 200 grains. Thereafter the dose is increased by 2 or 3 Gm a day until the p_H of the urine is from 7 to 7.6. Dosages of from 30 to 40 Gm or 500 to 800 grains a day, and even higher, may be reached with safety. The weight generally increases markedly at first and an extremely marked, even alarm-

Chart 1 — Patient made complete recovery. Note marked diuresis at maximum intake of alkali.

ing, initial increase of the edema is practically a constant feature in all cases. Estimation of plasma bicarbonate at frequent intervals is necessary at this stage. In spite of the marked increase of the edema, it is necessary at this point to increase the dosage of alkali fearlessly until the plasma bicarbonate reaches a normal level or beyond and to keep the dosage continually high for some time, unless symptoms of toxic alkalosis, such as tetany, heart weakness or excessive diarrhea or vomiting, make a diminution of the dose especially of the potassium salts imperative. A remarkable diuresis usually sets in shortly after the height of the dosage has been reached, the p_H of the urine is between 7.6 and 8.3 and the plasma bicarbonate is at normal level or above. This diuresis usually continues and often in an amazingly brief time causes complete loss of edema, marked diminution or complete disappearance of albumin from the urine and great reduction in lipemia.

Three dangerous symptoms must be looked for and guarded against at this stage of the case. Tetany and even convulsive seizures may develop. Symptoms of dangerous heart weakness may appear or excessive vomiting and diarrhea may develop. Tetany can be

prevented or usually relieved by the repeated intramuscular use of calcium chloride in a dosage of 0.05 Gm. For the heart weakness and excessive diarrhea a diminution of the alkali, particularly the potassium salts, is advisable and often imperative. It is seldom necessary to reduce the dose by more than one third of the maximum amount, and it is often sufficient to reduce only the potassium salts. We have found it necessary to reduce these sharply in the face of dangerous symptoms.

Even in the face of threatening dangers, the success of the treatment depends on a bold and fearlessly continued use of relatively high doses of alkali. When active diuresis has set in, it is unnecessary to increase the alkali further, but the high dosage must be maintained at all costs until the edema has entirely disappeared and the volume of urine has gradually fallen to normal. It may take from ten days to several weeks before this is accomplished, but the dose must not be reduced before this stage is reached. Any reduction commonly leads to a return of the edema, albuminuria, oliguria and even complete anuria. The latter condition is liable to occur if all alkali is withdrawn rapidly or completely.

After the urinary volume has returned to normal, a gradual reduction of the dose may be effected. Any return of the symptoms must be met at once by a resumption for at least a few days of the maximum dose. A substantial dose of alkali should be continued for a considerable period after all edema has disappeared and the urine has cleared entirely of albumin, in order to insure against return of active symptoms.

The high alkali treatment will not relieve every case of nephrosis, but it will almost certainly relieve the troublesome edema and reduce or stop the proteinuria. It cannot prevent or significantly modify the serious complications such as pneumococcal or streptococcal pneumonia or peritonitis or cellulitis, but there is no

Chart 3—Patient eventually completely recovered but shows the relapses due to severe intercurrent infections

doubt that the removal of edema fluid from the tissues must afford a considerable measure of protection against the development of these infections.

In a series of forty cases reported by Osman, thirteen patients with nephrosis ranged in age from 2 to 7 years, one with a mixed form of the disease was over 13 years. In nearly all the cases the disorder had

existed from six months to over a year and was characterized by excessive anasarca and ascites. Of the fourteen cases, five were completely cured, one was permanently improved and eight were fatal. Three of the deaths were due to pneumococcal peritonitis, one patient died from tetany and one from intercurrent summer diarrhea after recovery from the renal disorder. Two died from relapses after initial success with the treatment and one died without showing any response whatever to the treatment.

Our series at the Bobs Roberts Hospital comprises seven cases. Of these, three of the patients have apparently completely recovered except that in two of the cases a moderately severe infection of the upper respiratory tract, especially acute sinusitis, is followed by a slight transitory return of the edema. Two of the patients have been free from all symptoms for a period of more than three years.

Of the four cases which were fatal, only two were really true cases of nephrosis as shown by autopsy. Two were of the mixed form, showing extensive renal damage. All of them had shown considerable edema before admission to the hospital. Two patients died of pneumococcal peritonitis which developed shortly after their admission to the hospital and before the high alkaline treatment had been well started although in one of the cases marked diuresis had set in. The

Chart 2—Patient had apparently made complete recovery but eventually succumbed to an acute hemolytic streptococcus infection

Estimation of the plasma bicarbonate is probably the best check on favorable or unfavorable response to the treatment. It is commonly found that, if treatment is omitted or improperly managed before the "cure" is complete, a much larger dose is required in a second attempt to secure the same result if it can be obtained at all.

third child died from heart failure within forty-eight hours after admission to the hospital and before effective therapy could be started. The fourth patient, one with true nephrosis, had responded remarkably and repeatedly to the treatment and had apparently completely recovered when a hemolytic streptococcus throat infection suddenly developed, followed by pneumonia and general peritonitis, death occurred within a week after the onset of the illness. Autopsy was refused.

Except for the prompt treatment of minor infections and reasonable supervision of the diet, no particular management seems to be necessary once the patient has recovered.

The favorable experience that we have had in the few cases in which this form of treatment could successfully be inaugurated and followed seems to confirm the favorable results reported by Osman and led us to believe that the use of the high administration of alkalis is probably one of the best forms of therapy available for the treatment of chronic nephrosis and the relief of some of its most troublesome symptoms and should be attempted in all cases that do not readily yield to less drastic measures.

ABSTRACT OF DISCUSSION

DR. A. GRAENE MITCHELL, Cincinnati. One of the most important considerations is to determine whether the patient has what the authors referred to as pure nephrosis. I believe there is such a condition although I think it is difficult to diagnose, and often it can be distinguished from nephritis only after long observation. I have always been discouraged with the treatment of nephrosis. It has given me a feeling of futility. In Cincinnati my colleagues and I have made a definite attempt to try to find out something about it. Over a period of some years we have kept in the metabolism ward several patients suffering from what we originally thought was nephrosis. We discovered later that in some instances the patients had a true nephritis. The most important fact that I discovered was how much it costs to run a metabolism ward. Secondly, we came to the conclusion that we really knew little about what to do for the patient with nephrosis. Theoretically, the condition has bothered me tremendously. The arguments that have led to acid therapy and, on the contrary, to alkali therapy have never been entirely clear to me. Practically, I have sometimes felt that a patient who did not respond to acid therapy would sometimes respond later to alkali therapy or that the reverse of this might happen. After considerable observation I came to the conclusion that the patient did his tricks of retention or loss of fluid on the same regimen and that what I was doing had no particular effect, so that in my innocence I felt that I was doing rather little to help. It is obvious that the authors have been more courageous and more persistent in alkali therapy than I have been and perhaps that is the reason they have obtained results. The danger of alkali therapy should be stressed. I have reached the point where I feel that alkali should never be given unless one has the opportunity to observe the patient under controlled conditions. Close clinical observation is not enough since it is difficult if not impossible, at times, to distinguish alkalosis from acidosis. Alkali therapy, then, should be carried out only when one has the opportunity to determine frequently the carbon dioxide content of the patient's blood. I have had in the last year four infants with alkalosis on the basis of alkali therapy. Three of these patients died.

DR. FREDERIC W. SCHLUTZ, Chicago. I quite agree with Dr. Mitchell that it is difficult to tell whether one is dealing with a case of true nephrosis or some other form of nephritis. The clinical picture largely must guide one. No claim is made that the alkali therapy will benefit every form of nephritis. It has been the experience, however, of Osman and also our own that it will benefit any case of nephrosis or nephritis in which there is a great deal of edema and proteinuria. These two symptoms are always markedly benefited by the treatment, and particularly so in the nephrosis case. Every one who uses the treatment will be startled by the rapid increase of edema

above the amount at the start of the treatment. It seems as though one is doing the patient more harm. It is most important to remember that one must fearlessly increase the salt intake and certainly persist in the use of large amounts in the face of this increase. Only decrease the salts when dangerous symptoms supervene. These are marked diarrhea, evidence of cardiac weakness and major manifestations of tetany. A moderate showing of tetany need give no alarm. It is the potassium salt that must first be reduced and sometimes the only salt that needs to be reduced. It is always necessary to check the plasma bicarbonate when using this treatment. If the plasma bicarbonate approaches normal or slightly above normal levels, the treatment is usually adequate and favorable symptoms will develop. Unless toxic symptoms supervene, the salt mixture can be fearlessly increased until the plasma bicarbonate level approaches normal. This form of treatment should not be carried out in any case of nephrosis or nephritis unless the plasma bicarbonate can be checked at frequent intervals.

MUCOSAL PATTERN TECHNIC AND KYMOGRAPHIC RECORDS OF THE ESOPHAGUS AND STOMACH

EDWARD HOLMAN SKINNER, M.D.

KANSAS CITY, MO

Two newer methods of roentgen technic, useful in gastro-intestinal diagnosis, have enjoyed extensive exposure in the literature of roentgenology and on programs of roentgen societies. It is proposed to expose these methods to the members of the general profession and, at the same time, to inquire critically into their values.

The mucosal pattern, the relief picture or the compression technic of the mucous lining of the gastro-intestinal tract is secured by fluoroscope or roentgenogram after manipulation and gravity have adapted a thin, mucilaginous, opaque medium to the mucosal folds of the esophagus, stomach or small or large intestine. It is a study of the intimate morphologic detail of the mucosa. The regular, bulkier barium sulfate meal provides the diagnostic factors of contour and function and will provide conclusive diagnostic facts in a major portion of appropriate cases. The mucosal pattern technic amplifies the routine examination in certain details of the actual ulcer and cancer or characteristic diagnostic patterns, such as esophageal varices or chronic gastritis.

There are inherent dangers to the roentgenologist in the mucosal pattern technic because of the prolonged exposure of the fluoroscopic studies which may be necessary to secure or identify the favorable filling or pattern which he wishes to record permanently by the roentgenogram. Sometimes this danger is greatly increased among physicians who complete their own roentgen examinations, because they fail to impose on themselves the requirements of eye accommodation, because they do not have the apparatus that roentgenologists know is essential for success with this method and, more pertinently, because they lack a studied familiarity and experience with normal and abnormal mucosal patterns.

Special apparatus is required (1) so that the favorable mucosal pattern can be achieved by compression, position and posture and (2) so that the small, aimed roentgenograms are secured at the right instant. It must be possible to switch from fluoroscopic image to proper radiographic technic instantly. The expense of

this technical requirement seems to preclude the adoption of this technic by others than roentgenologists.

There are, however, two particular situations in gastro-intestinal diagnosis in which the mucosal pattern technic can be useful without special apparatus or extensive roentgen education. The vagaries of actual and artificial pattern fillings throughout the gastro-intestinal canal are such as to impose great responsibilities of study of and experience with normal and abnormal mucosal patterns on every physician who would pursue these examinations. Undoubtedly the method may be reserved to the skilful roentgenologist and to the gastro-enterologist whose mental and mechanical equipment for roentgen diagnosis rank with those of the qualified roentgenologist.

These two situations of practical and easy application of pattern technic involve (1) the lower end of the esophagus and (2) the general mucosal pattern of the stomach.

Esophageal varices produce a characteristic shadow of uneven, tortuous mucous membrane. The normal esophageal mucosa shows long, thin, evenly spaced lines running parallel throughout this lengthy tube. The ordinary heavy barium sulfate meal masks both the normal and the abnormal mucosal pattern. Any thin, mucilaginous opaque mixture swallowed by the patient while in a favorable, prone, esophageal position on an x-ray table will secure the roentgen details by fluoroscope or roentgenogram. It is not an evanescent, transitory pattern because it can be identified by succeeding films as long as the barium mucilage remains in the esophagus. No particular opaque mixture is required, although there are American proprietary products that are extremely smooth and easy to use. There is no necessity for advertised foreign opaque mixtures.

The mucosal pattern of esophageal varices is produced by the enlarged tortuous veins protruding into the lumen of this tube. The lumen may be widened if the varicose condition is extensive. Varices can be pressed out by peristalsis and by increased intrathoracic pressure. Cancer and ulcer are easily differentiated from this characteristic varicose pattern by the usual extensiveness of the varices and the limited area of cancer or ulcer. The normal thin mucosal lines of the esophagus persist with cancer or ulcer except at the limited area of new growth while with varicose patterns the only normal lines are at the upper part of the esophagus. Varices are usually encountered with cirrhosis or fibrosis of the liver. Unrecognized cirrhosis has been inferred from this isolated and characteristic x-ray shadow. Esophageal varicosis is not an infrequent condition. One roentgenologist (Schatzki) found forty-five cases in two and one-half years.

Chronic hypertrophic gastritis provides enlarged, deep, stiff, thick rugae. Such rugae may be normal at the greater curvature of the pars cardica and media but are usually diagnostic of chronic gastritis at the pars pylorica and at the lesser curvature. Differential diagnosis is required for lymphoblastoma or cancer. Polypoid growths protrude into the gastric lumen. Increased mucous secretion produces a marbled appearance of the gastric contents. Nonopaque food residues and air bubbles offer little difficulty to the experienced eye. Extensive ulceration of the stomach is rare. The isolated ulcer or cancer is recognized by the identification of the lesion amidst an otherwise normal mucosal pattern.

Again, one can achieve this characteristic gastric diagnosis of enlarged, deep rugae by a thin mucilaginous opaque meal that is allowed by posture and compression to adapt itself to the gastric mucosa. Rolling the patient, forced breathing and moderate compression easily provide the pattern picture when roentgenograms are taken with the patient in favorable postures, both with and without pressure technic.

That I have focused attention on two particular uses of mucosal relief technic does not mean that its usefulness is thus confined. The point is that its usefulness beyond these two situations is reserved for the roentgen specialist who is equipped with experience, apparatus and training in the vagaries of the normal gastric and intestinal mucosa. The time required to complete the mucosal relief examination places it beyond or outside routine roentgen examinations. It is reserved for duodenal ulcers which are very small, for cases which offer technical difficulties of spasm, debatable niche formation, and for cases of stout or spastic type. Even among experts using this method there is the debatable field of active ulcer niche and healed scarr, especially in the duodenum.

Kymography contrasts with the mucosal pattern technic in that it is entirely a record of function exhibited at a chosen margin of an organ. It is particularly useful for the study of the pulsating margin of the heart and aorta. There are many inherent errors and difficulties. The task of interpretation requires meticulous attention to shadow margin, and the personal equation of the roentgenologist looms large. Again, special apparatus is required. This fact, and the demands of special interpretation, seem to make kymography essentially the function of the qualified roentgenologist.

Kymography consists of placing a moving slit grid between the patient and the film during an exposure of an arbitrary time period. One must study the resulting surrealist exposure with caliper and rule to compare the recorded movement displayed by toothlike serrations at various, identified, moving margins of an organ. The cycle of cardiac movements is usually completed within a second plus, the patient can hold his breath and avoid the imposition of shadows of respiratory movements on cardiac movements.

The gastric motility is normally twenty-two seconds and therefore respiratory and cardiac movements must be subtracted from the essential gastric movements. This subtraction is very difficult. The value of kymography in gastric diagnosis would be for the study of the muscular movement of a portion of the wall where one suspected an early cancer. The method requires that the particular area be recorded by kymography in profile. Gastric peristalsis must be functioning at the time, the opaque filling must be generous and perfect, the subtraction of respiratory movement may be possible, but cardiac movement is persistent during the briefest period of any practical gastric kymograph. Kymography, being a record of function or movement must persist over a sufficient period of gastric peristalsis to permit analysis by mensuration of the movement of shadow margin. The method has no advantages over the fluoroscopic study of motion in the presence of a grossly visible ulcer or cancer. There are no advantages over the mucosal relief technic for the small lesion. The only advantage that kymography would add to diagnosis of early cancer is the study of the mucosal area in the gastric outline. This area is comparable to the area in the ventricular or auricular wall that I

lost its usual muscular activity owing to extrinsic adhesions (cardiolysis) or intrinsic loss of tone (coronary infarction)

While there are no dangers to the roentgenologist in kymography of the stomach, there are the dangers to the patient of cutaneous reactions from the length and strength of the prolonged exposure required. Ordinary 1 mm aluminum protection to the radiographic x-ray beam is not sufficient.

Enthusiasm for gastric kymography is not warranted. The theoretical possibilities are overshadowed by actual dangers of technic and physiologic embarrassments to interpretation.

These brief but critical objections to gastric kymography must not be confused with disparagement of the practical values of cardiac kymography. Cardiac kymography has many useful purposes and carries no dangers to patient or operator. It has been exposed by many excellent articles to the general and specialty groups. It was my enthusiasm for cardiac kymography and my hope for a method of estimating muscular embarrassment at small portions of the gastric wall in cases of early gastric cancer that led me astray. The mucosal relief study fails to identify movement and depends on actual morphologic defects. Gastroscopy enters the field of early diagnosis of gastric cancer with the best wishes of those who hope for positive identification of the lesion at a period when its complete ablation is a surgical practicality in a larger group of cases than seems possible now.

Professional Building

ABSTRACT OF DISCUSSION

DR LESTER LEVIN, Buffalo. Hirsch, Moore and Scott have shown the method to be of great value in the diagnosis of obscure cardiac lesions, but only a negligible amount of work has been done on the gastro intestinal tract, particularly in this country. So far as the stomach is concerned the method is strictly in the experimental stage. The kymographic records are complicated and little is known about even the interpretation of the normal. Experience has been entirely too limited. I would hesitate to attempt to make a diagnosis of early carcinoma of the stomach by kymography that could not be made by our present methods. I am, however, optimistic about its future, and feel that within the next few years it may prove to be a procedure capable of detecting lesions earlier than can be done at this time. The study of the stomach and the esophagus by the mucosal relief method should be a routine procedure with every roentgenologist. Esophageal varices are diagnosed only rarely by a complete filling of the esophagus with barium sulfate. This is due to the fact that varices are hidden by the density of the opaque meal. The varices, however, certainly are more common than suspected and are more easily demonstrable when careful technic is carried out by the relief method. The veins are seen to project tortuously into the lumen of the esophagus. One should rarely miss esophageal varices when the relief method is employed and painstaking technic is required. Concerning chronic gastritis, the roentgen mucosal method may show the change that occurs in the hypertrophic variety in a fairly large percentage of cases, but it must not be forgotten that chronic gastritis may be present without any deviation from the normal in the mucosal pattern. When considering the question of atrophic gastritis, one is stepping on rather dangerous ground when one attempts to diagnose that condition, because the thin mucosal folds that may be indicative of atrophic gastritis are often seen in perfectly normal persons and also in certain persons suffering from blood dyscrasias, particularly pernicious anemia. The study of the rugae may disclose the presence of a peptic ulcer that may escape detection entirely when the usual contrast meal is given and, likewise occasionally, in relatively early carcinoma. Dr Skinner's paper is valuable because he has so strongly stressed the advantages of study of the mucosal pattern. It often con-

firms or establishes a diagnosis when the large contrast meal fails to do so. It is, however, advisable to conduct gastrointestinal examinations by both methods.

DR WENDELL G SCOTT, St Louis. Dr Skinner has ably surveyed the field of kymography in the study of gastric lesions. Dr Sherwood Moore and I have used the method in a few cases. The kymographic method in gastro enterology is limited by the slow movements of these structures and by the long exposure time. The method at this stage is not a practical clinical procedure. It can be used for experimental work, particularly in a painstaking investigation of the movements of the rugae, gastric silhouette and duodenum.

YELLOW BONE MARROW EXTRACTS IN GRANULOCYTOPENIA

PRELIMINARY REPORT

C M MARBERG, PH D
AND
H O WILES, PH D
CHICAGO

At the Milwaukee session of the American Medical Association, in 1933, Dr C H Watkins of the Mayo Clinic announced that he had obtained favorable results on treating patients suffering from granulocytopenia with yellow bone marrow. He reported that a monocytosis first occurred, which was followed by a gradual increase in polymorphonuclear neutrophils. Usually a reaction occurred within twenty-four to forty-eight hours after ingestion of the bone marrow. An account of this work has not yet been published by Dr Watkins.¹

Shortly after this announcement Dr M J Flipse of Miami, Fla., also obtained very encouraging results with the marrow but found that the large dose which is necessary was undesirable, and it was through his suggestion and that of Dr Fenger of Armour & Co that we sought to prepare an extract which would be free of the large amount of fat that is present in the refined marrow. Such a concentrate was prepared by extracting the unsaponifiable portion of the marrow and dissolving it in a bland oil for oral administration. The equivalent concentration of 2 Gm of marrow per drop has been found quite satisfactory for clinical use.²

There being as yet no satisfactory method for producing agranulocytosis in experimental animals, it has been necessary to test the activity of our preparations on the occasional clinical cases that have been available. We are greatly indebted to the physicians who have cooperated with us in this phase of our work.

Up to the present time the extract has been administered to twenty patients with granulocytopenia, and in all but seven there has been a rise in the number of granulocytes, usually with a return to normal figures. In fact, if active infection persists during the period of treatment the granulocytes may rise to figures far above normal. Of the seven patients who did not give a satisfactory response, two were later found to have

From the Otto S A Sprague Memorial Institute and the Department of Pathology, University of Chicago.

¹ Dr Watkins has published an account of the use of bone marrow in anemia (J A M A 95:587 [Aug 23] 1930) in which he reported a remarkable response in one case of agranulocytic angina.

² Recently there has appeared a paper by Joseph Zichus (Granulocytopenic Fractions of Yellow Bone Marrow, J Lab & Clin Med 22:231-237 [Dec] 1936) the data of which indicate that he partially saponified the marrow removing only part of the fat. He does not acknowledge our prior work (paper read before the Medicinal Section of the American Chemical Society, Cleveland, Sept 11, 1934) which was reported in preliminary form in 1934. His experimental work and method of testing which was carried out on rabbits will be criticized in more detail when this work is published in full.

aplastic anemia, in four a differential diagnosis was not made, and the last had diabetes and appendicitis in addition to the granulocytopenia. The rise in granulocytes usually begins within twenty-four to thirty-six hours, as contrasted with the effect of pentnucleotide, which is not usually manifested in less than from four to five

Chart 1 (case 1)—Response of leukocytes (solid line) and neutrophils (dotted line) to yellow bone marrow

days. We are informed by Dr. Flipse, who has used our concentrate in several cases, that he has obtained similar results.

To illustrate the characteristic effects of the bone marrow extract, brief abstracts of two typical cases are presented.

CASE 1—Miss E. D., a patient of Dr. Maurice Simkin, was diagnosed as having "agranulocytic angina." Chart 1 indicates slight but transitory response to pentnucleotide together with liver extract and "extralin." The patient objected to her reactions to pentnucleotide, saying that she would "rather die than have another injection," whereupon all medication was discontinued in favor of yellow bone marrow. Two enteric coated capsules (0.5 Gm each) of the nonsaponifiable residue were given each of two days. There was no response. It was later learned that the capsules were too heavily coated and would not open in the gastro-intestinal tract. When the oil solution was used orally a prompt response was obtained—within thirty-six hours—and a maintenance dose could be established. When the extract was discontinued the count fell immediately but increased rapidly again on resumption of

Chart 2 (case 2)—Response to administration of yellow bone marrow

medication. The granulocyte/lymphocyte ratio also became normal on extract therapy. Clinical improvement was coincidental with the improvement in the blood picture and she was discharged. The patient had a recurrence in March 1937 but improved rapidly when given the extract. A response almost identical with the responses recorded in chart 1 was obtained and the angina cleared up within seventy-two hours; the leukocyte count rising from 3500 to 7500 on medication with the extract.

CASE 2—Mrs. M. J. had been seen occasionally in the patient service of the Chicago Lying-in Hospital with a complaint of menorrhagia and dysmenorrhea. She had been taking a proprietary medicine containing aminopyrine for the latter. When examined Sept. 11, 1936, she showed no remarkable symptoms except those mentioned. The leukocyte count was 4,800 (chart 2).

She was admitted for treatment September 14 with acute tonsillitis and pharyngitis, a temperature of 104 F and a leukocyte count of 2,400, which fell later to 925. A diagnosis of probable agranulocytic angina was made and yellow bone marrow extract therapy was begun immediately; no other hematopoietic stimulant was given.

The following morning the count was between 700 and 1000 white blood cells (3 per cent neutrophils) but had risen by evening (twenty-four hours from the beginning of treatment) to 3,300 white blood cells, 83 per cent lymphocytes, 12 per cent monocytes, 1 per cent metamyelocytes, 2 per cent band forms and 2 per cent segmented neutrophils. The temperature had fallen to normal by September 17, clinical improvement followed immediately on the improving blood picture. The peak of the bone marrow response was reached September 21 with 11,500 white blood cells and 65 per cent neutrophils of which 52 per cent were segmented, 12 per cent band form and 1 per cent myelocytes and metamyelocytes. The patient was discharged in good condition September 23. Subsequent blood counts were within normal limits.

A more detailed report of the chemical work and clinical observations will be presented in a subsequent paper.

THE DIAGNOSIS AND TREATMENT OF UNDULANT FEVER

CARL E. ERVIN, M.D.

AND

HENRY F. HUNT, M.D.

DANVILLE, PA.

The purpose of this paper is to discuss briefly the diagnosis and treatment of undulant fever. Time does not permit a full review of all the therapeutic measures which have been offered, therefore our remarks will be limited mainly to a further discussion of the use of intravenous injection of killed typhoid and paratyphoid organisms in the treatment of this disease.

The diagnosis of undulant fever is dependent on the laboratory for final confirmation. In this connection certain diagnostic problems confront the physician. The patient may present some of or all the classic symptoms, namely, irregular fever, profuse night sweats, weakness, nervousness, epigastric pain, muscle vomiting, arthralgia and, in addition, some complication, such as involvement of the central or the peripheral nervous system or suppurative arthritis, and yet the blood may show no agglutination for organisms of the brucella group. This negative reaction may be due to the insufficient lapse of time for the development of specific agglutinins. The length of time varies widely, usually from two to several weeks. However, the agglutination may never at any time become positive.

A positive agglutination reaction must always be correlated with the symptoms and physical signs shown by the patient. There are numerous reports in the literature of the presence of *Brucella* agglutinins in the blood of persons who have no other evidence of disease. One of us (Hunt)¹ in a study of 1,000 un-

1. Hunt, H. F., and Nell, M. E. A Study of Native *Brucella* in Human Blood Sera from Virginia. *M. J.* 10: 433-435 (1937).

lected samples of blood found 89 per cent of the serums to agglutinate specific *Brucella* antigens in a dilution of 1/80 or above. An analysis of clinical and other laboratory observations on this group of patients will be published at a later date. One can only conjecture as to the origin of such agglutinins. Many theories have been advanced to explain their presence in the blood of apparently normal persons, but to date none of the theories have been definitely proved or accepted. Veterinarians, packing house workers and breeders of live stock often are found to have positive agglutinins in their blood. Their presence is thought to indicate a past infection or recent exposure to infected materials.

The determination of opsonocytaphagic power of the blood for *Brucella* is another laboratory procedure that may be employed in the diagnosis of undulant fever. A fresh bacterial suspension prepared each day from a pure culture of organisms of the *Brucella* group is essential for this test. Any one of the three specimens of *Brucella* is suitable, but the cultures should be checked frequently for "fastness" to phagocytosis. It occasionally happens that strains of *Brucella* tend to become fast to ingestion by cells.

Huddleson, Johnson and Hamann² have reported a method for determining the opsonocytaphagic power of the blood which is a modification of the Leishman³-Vetch⁴ technic. The method of recording phagocytic activity as outlined by the first mentioned authors consists of counting a total of twenty-five cells in different sections of the spread and recording each cell as follows: negative when no phagocytosis occurs, slight when from one to twenty bacteria are seen in the cell, moderate when from twenty-one to forty bacteria are seen in the cell and marked when the number of bacteria in the cell is above forty.

The interpretation of the results obtained by this test in the hands of the inexperienced may be as misleading as the results of the agglutination test. A more detailed report on this procedure will be found in Huddleson, Johnson and Hamann's² article and in Huddleson's⁵ monograph on "*Brucella* Infections in Man and Animals."

Blood culture is helpful in many instances but as a diagnostic measure is slow. Special equipment is required and will not be found in many laboratories. The absence of leukocytosis is helpful. In fact, there may be leukopenia. We have usually found a normal differential count.

We believe that the intradermal test either with a *Brucella abortus* vaccine in a 1/10 dilution or with soluble nucleoprotein fraction of similar origin is helpful in diagnosis. The reaction must be regarded as negative unless it remains positive for a week or ten days (fig 4). Frequently the reaction remains positive for eight or ten weeks, and the fading mark may be visible for a year. Too strong a solution is to be avoided lest central necrosis develop at the site of injection. The intradermal test depends on tissue sensitivity induced by the presence in the body of organisms of the *Brucella* group. A positive reaction may result from frank *Brucella* infection or from

repeated small infections inadequate to produce fever. So, too, this test is invalidated unless it is supported by active symptoms.

Enthusiasm for making a diagnosis of brucellosis may cause the physician to overlook such common infections as tuberculosis, typhoid fever, subacute bacterial endocarditis, hidden malignant growths, rheumatic fever, otitic infections in children and less common conditions such as meningococcal septicemia. Perhaps the most useful procedure is to entertain the diagnosis of brucellosis in all cases of unexplained fever or prolonged disability, especially of the neuroasthenic type.

The behavior of the temperature shows the widest variations from sudden onset with high elevation to an insidious beginning, barely noticeable to the patient. Two of our twenty-two patients showed sudden onset with regularly recurring chills. In one instance the chills occurred every forty-eight hours and in the other every seventy-two hours. Perhaps the most characteristic thing about the fever is the constant irregular-

Fig 1 (case 1)—The high and the low temperature in twenty four hours before during and after treatment. Although fever had been present for seven months recovery was prompt and complete.

ity, so that it need not be confused with that of typhoid, empyema, tuberculosis or other common infections.

TREATMENT

One finds in reviewing the literature that most successful treatments are accompanied by a sharp thermal reaction. This is true regardless of whether the treatment given is administration of a vaccine, toxic filtrate, specific serum, chemical or foreign protein or fever induced by mechanical appliance.

Debono⁶ noted that after intravenous injection of filtrate prepared from brucellin and mehtine the temperature reached a maximum in seventeen or eighteen hours and then fell the following day. After two or three such treatments he was able to reduce the temperature to normal. In one of our cases a favorable drop in temperature occurred after the sharp thermal reaction induced by mercurochrome injected intravenously and sterilized skimmed milk injected intramuscularly. Prickman and Popp⁷ used the Simpson-Kettering Hypertherm to induce fever in three cases of brucellosis. The results, while somewhat delayed were generally satisfactory. Carpenter

and Boak,⁸ in a review of the treatment of human brucellosis, aptly remarked that the attribution of favorable results to a specific effect of the vaccine is not justifiable. In their opinion the good results depend on the intensity of the generalized systemic reaction evoked by the injection, the type of vaccine playing little part. These authors, further, added a word of caution regarding the possible toxic action of the vaccines. It must be noted, however, that numerous cures have been reported when no thermal reaction was induced by the medicament. One must not forget that spontaneous recovery often takes place. In this connection we quote from one of our colleagues with whom we had discussed fever therapy for a case of active brucellosis. She wrote "Our patient had such a complete remission (the temperature dropped from 104 F to normal, with complete subsidence of all symptoms) that we were not justified in using typhoid vaccine. If I had used the vaccine a week sooner we would have thought it a fine remedy." Had this correspondence occurred earlier, the patient would likely have been added to the list of those successfully treated by a certain method.

REPORT OF CASES

The following cases, in addition to the ten others already reported, represent our experience with the use

Fig 2 (case 2)—The high and the low temperature in twenty four hours before during and after treatment. Recovery was prompt and complete. This chart illustrates regularly recurring paroxysms of chills and fever.

of mixed typhoid vaccine⁹ injected intravenously.¹⁰ We include one control case, in which this agent was not used.

CASE 1—T V, a man aged 30, an undertaker admitted Sept 14 and discharged Sept 26, 1936, became ill seven months before admission with sudden fatigue followed by low grade fever and gastro intestinal distress, loss of appetite, furred tongue and chronic constipation, tenderness over the right upper quadrant, bloating and the loss of 31 pounds (14 Kg). Physical examination was not helpful beyond revealing evidence of the loss of weight. The temperature ranged from 100 to 101 F. Agglutination was negative, the intradermal reaction strongly positive. Treatment consisted of three injections of typhoid vaccine, 30 million organisms. The temperature (fig 1) remained normal after the third injection, and recovery was prompt and complete. The illness lasted thirty-two weeks; it terminated two weeks after treatment. At a follow-up examination May 9, 1937 agglutination was negative and the intradermal reaction moderately positive.

CASE 2—H F, a man aged 19, a garage mechanic, admitted July 12 and discharged Aug 21, 1936 became ill three weeks before admission with chills which occurred quite regularly

every two to four days, sweats, pain in the ribs and headache. Physical examination gave entirely negative results. He had four chills after admission, at seventy-two hour intervals. On July 13, the twenty-second day after the onset of illness, agglutination for *Brucella abortus* was negative, but nine days later it was found to be positive in a titer of 1:200. The leukocytes numbered 5,500 and the neutrophils 71 per cent. Treatment consisted of seven injections of typhoid vaccine in 50 to 80 million organisms. The temperature dropped to normal after the first injection, and the patient had no more chills (fig 2). He recovered completely and returned to work on the day after he was discharged from the hospital. The illness lasted five weeks. At a follow up examination May 9, 1937, the weight was 160 pounds (72 Kg), a gain of 41 pounds (13 Kg). Physically the patient was entirely normal. Agglutination was negative in all dilutions. The intradermal reaction was negative.

CASE 3—F L P, a man, aged 37, a minister, admitted Jan 8 and discharged Jan 25, 1937, had been ill twenty-six days. The onset was gradual with generalized pains in the body associated with chilly sensations and a temperature from 102 to 104 F. The patient was nauseated and vomited the first few days. He had a constant dull headache and several attacks of vertigo and fainted once. He had no pains in the joints but felt feverish and extremely weak. Physical examination was not helpful. A blood count showed hemoglobin 84 per cent, red blood cells 5,320,000, leukocytes 11,150, neutrophils 61 per cent, eosinophils none. Agglutination was

negative for *Brucella abortus*. The intradermal reaction was strongly positive, the temperature varied from 100 to 101.4 F for one week. The treatment consisted of two injections of 30 million typhoid organisms. The temperature was normal after the first injection. The patient returned to work February 17. The illness lasted eight weeks, four weeks after treatment. At a follow up examination May 13, agglutination and the intradermal reaction were negative.

CASE 4—G W L, a man, aged 45, a farmer, admitted June 14 and discharged June 19, 1936, readmitted Sept 18, 1936 and discharged October 14, became ill six months before admission, with grip. This was followed shortly by chill fever, sweats, headaches, backache, malaise and generalized stiffness of joints and loss of 11 pounds (5 Kg). Physical examination was not helpful. Agglutination for *Brucella abortus* was positive in a titer of 1:500. The temperature on admission was 99.4 F. It promptly returned to normal and we thought the patient was experiencing a natural remission so he was allowed to go home untreated. His fever returned and the other symptoms failed to clear up. After a second admission he was given seven injections of from 30 to 127 million typhoid organisms. Since he left the hospital his temperature has remained normal and he has been free from symptoms except for nervousness which is quite unusual to him. The illness lasted thirty-two weeks. At a follow up examination May 12, 1937 agglutination for *Brucella abortus* was positive in a titer of 1:500, the intradermal reaction was ++ and the weight was 154 pounds (70 Kg), a gain of 17 pounds (8 Kg). The patient said "I can't do a day's work, my legs give out." There was slight dyspnea on exertion. The results were only fair.

CASE 5—R W, a man, aged 18, a student admitted Sept 13 and discharged Sept 18, 1936 became ill August 1 with lethargy, loss of weight, lack of ambition, loss of appetite, frontal headache, pain in the legs, chills and a rise in temperature in the afternoon for one month. He had such night sweats one week that he frequently had to change

night clothes. Physical examination was not helpful. The leukocytes numbered 3600. The temperature varied from 99 to 103 F. Agglutination for *Brucella abortus* was positive in a titer of 1:500. The treatment consisted of an injection of 40 million typhoid organisms September 17 and two similar injections after the patient returned home. The temperature was normal after September 20. The patient was ill twenty-seven days before treatment was begun and had an immediate recovery. May 12, 1937, he was in perfect health and physical

Fig. 3 (case 9)—The high and the low temperature in twenty-four hours. The temperature returned to normal after the second injection. Recovery was prompt and complete.

examination gave entirely negative results. He had gained 30 pounds (13 Kg). Agglutination was positive in a titer of 1:500. The intradermal reaction was moderately positive.

CASE 6—H. B., a man, aged 43, an undertaker, admitted April 23 and discharged May 21, 1937, had been ill four months with weakness and nervousness which rendered him almost unable to carry out his work, chills and sweats, continuous pains in the joints but no swelling, pain in the region of the right sciatic nerve and weakness in the right sacro-iliac joint. He said 'I am sore all over my flesh is like a raw piece of meat'. Examination showed that he was apprehensive and fairly well nourished with chronic tonsillitis, periapical dental infection and tenderness over the right sacro-iliac joint. The temperature ranged from normal to 101.2 F. Agglutination for *Brucella abortus* was positive in a titer of 1:160. Treatment consisted of four injections of typhoid vaccine, from 60 to 160 million typhoid organisms and tonsillectomy. With the exception of nervousness unnatural to him the symptoms completely disappeared in sixty days. May 12 agglutination was negative and the intradermal reaction strongly positive. The patient was still nervous.

CASE 7—S. M., a nun, aged 27, admitted July 3 and discharged Aug. 31, 1936 had been ill six months. The illness began with nervousness, occasional night sweats and frequent excessive perspiration during the day, constant pain in the region of the right sciatic nerve and loss of 12 pounds (5 Kg). At physical examination she was practically afebrile and had slight nasal and pharyngeal congestion and tenderness over the right sciatic nerve. Agglutination for *Brucella abortus* was positive in all dilutions. Treatment consisted of one month of rest in bed and six intravenous injections of typhoid vaccine from 30 to 90 million organisms. The results were not immediately helpful and the benefits from treatment are doubtful although all symptoms disappeared during the following ninety days.

CASE 8—S. L., a woman aged 34, a school teacher (patient of Dr. Ralph W. Thunman, Schaefferstown, Pa.) in September 1936 began to have sleeplessness, irritability, nervousness, especially in the morning and fatigue. She was tired on arising in the morning and found it hard to do any work. Gradually her appetite disappeared and she lost 27 pounds (12 Kg) and had a low grade fever. She was seen first Nov. 16, 1936. Physical examination was not helpful except to provide evidence of the loss in weight. Laboratory examination showed red blood cells 3,800,000 and leukocytes 7,750. The temperature ranged from 99 to 100 F. Agglutination for *Brucella abortus* was positive in a titer of 1:80. The patient was hospitalized Jan. 4, 1937 and given 10 million mixed typhoid organisms intravenously. The injection was repeated

January 9, and the temperature dropped to normal, it remained so for one month and then varied from 99 to 103 F the fever being accompanied by chills. February 9 the patient was given 30 million typhoid organisms intravenously and five days later a dose of 50 million. The temperature promptly returned to normal. May 14, 1937, the patient had not gained weight but was relieved and was improving so far as the symptoms of undulant fever were concerned.

CASE 9—W. R., a man, aged 23, a grocery clerk, admitted Aug. 28 and discharged Sept. 1, 1936, became ill three weeks before admission with a tired feeling in the legs and a rise of temperature in the afternoon to from 101 to 102 F. Physical examination was not helpful. Agglutination for *Brucella abortus* was positive in a titer of 1:500. Treatment consisted of three injections of from 30 to 40 million typhoid organisms. The temperature remained normal after the first treatment (fig. 3). Convalescence was complete, and the patient has since been symptom free. He returned to work Oct. 1, 1936. At a follow-up examination, agglutination was positive in a titer of 1:500 and the intradermal reaction positive.

CASE 10—I. L. F., a man, aged 45, a veterinarian, admitted May 11 and discharged May 26, 1936, had typical undulant fever in 1929 with strongly positive agglutination. In that attack he had pain in the shoulders, vague abdominal distress, headache and 'giant urticaria'. He contracted the disease while caring for herds infected with Bang's disease. He had a fever for nearly a year and never recovered his health. On admission, seven years after onset, he still complained of pain in his shoulders and intercostal areas. In fact, he had been unable to carry on his business. He complained of annoying paresthesia, especially in the right elbow and the right thigh. It was not deemed advisable to give him typhoid vaccine on account of the duration of his illness.

COMMENT

It will be noted that the course of acute and subacute *Brucella* infection was apparently shortened by this method of fever therapy.

It is of interest that in our small series of twenty-two patients one finds three invalids, all with chronic infection of from one to seven years' standing (cases 11 and 12 of a former report and case 10 of this report). The second patient, a woman 51 years of age, was given treatment in August 1935 and did well in spite of her age and her illness of nearly one year until February 1937, when definite psychasthenia developed, which has incapacitated her as a housewife. Patient 10 of this series is an example of an untreated person now a sufferer from a neurasthenic condition, a common complication, as pointed out by several authors. Such complications should cause no surprise when one recalls the frequency of definite involvements of the central

Fig. 4 (case 4)—A positive reaction ten days after an intradermal injection of 0.1 cc of a 1:10 dilution of undulant fever vaccine.

nervous system in undulant fever. They include meningitis, encephalitis and various forms of neuritis.

The mechanism of recovery is still a speculation, as pointed out in previous communications.¹¹ We reported that from the hemocytologic standpoint the most significant changes which occurred after the intravenous injections of killed typhoid and paratyphoid bacilli were found in the total leukocyte, the neutrophil, the metamyelocyte and the lymphocyte count. These observations were made by obtaining a control count immediately before the injection of killed organisms. After the injection of the killed typhoid and paratyphoid bacilli complete blood counts were made at hourly intervals for a period of four hours, twenty-four hours after the injection was made another complete blood count was taken. With a few exceptions the blood counts were made by the same person and the differential counts in all instances were checked by one of us.

In the series of cases reported in this article a similar study was made of each patient's blood, and in every instance after the injection of the killed organism relative leukopenia occurred in the first hour followed by a return to the preinjection level after twenty-four hours. The response of the neutrophils closely paralleled the response of the total leukocytes. The metamyelocytes showed no initial increase but a steady increase during the first four hours.

The lymphocytes showed an increase in the first hour and a decrease in the following three hours. The post-injection twenty-four hour count revealed that the lymphocytes were near the preinjection level. All the hemocytologic changes were transient as evidenced by the fact that at the end of twenty-four hours the observations were practically identical with the preinjection observations.

While the observations reported in this study do not explain why the patients recovered we do feel that as they were infected with a specific organism the results obtained strengthen the theory that the injection of killed typhoid and paratyphoid bacilli stimulates a general nonspecific immunogenic reaction. This reaction is reflected in the altered blood picture, which indicates a response of the reticulo-endothelial system to the foreign proteins injected.

Such response may in turn be the fundamental reaction which is responsible for the production of resistance or immunity. While we do not know exactly where antibodies are formed our results suggest that the injection of killed typhoid and paratyphoid organisms is responsible for the production in the body of nonspecific antibodies of sufficient quality to enable the patient to overcome the disease. Of course one cannot discuss immunity without considering the role of the phagocytes in ridding the body of bacteria.

We do not maintain that injection of typhoid vaccine is the ideal treatment but we do feel that it is the most practical method available to the rank and file of physicians who find here and there a case of brucellosis. It saves the necessity of trying to locate the specific vaccine or serum and more cumbersome methods of inducing fever. We have no hesitancy in advancing this form of treatment in view of the fact that whatever the method used the benefit seems to depend on thermal reaction. Its contraindications, namely, advanced

arteriosclerosis, arteriosclerotic or rheumatic heart disease, and marked debility, are common to other forms of therapy.

CONCLUSIONS

1 The results in the treatment of acute and of acute undulant fever by the intravenous injection of killed typhoid and paratyphoid organisms in carefully measured and appropriate doses compares favorably with those of any other form of treatment.

2 Contraindications to its use are arteriosclerosis, arteriosclerotic and rheumatic heart disease, hypertension and marked debility. These conditions also contraindicate most other forms of treatment.

3 We agree with Carpenter and others that the benefit comes chiefly from fever, but the stimulation of antibodies may also be important.

4 The advantage is the low cost and the immediate availability to any physician anywhere.

ABSTRACT OF DISCUSSION

DR. WALTER M. SIMPSON, Dayton, Ohio: Soon after our studies in undulant fever were begun in 1928, we experimented with the therapeutic use of a *Brucella melitensis* abortus vaccine. We pointed out that the vaccine was effective only in patients who responded with at least three or four sharp febrile reactions which usually occurred after the dosage of the vaccine had reached from 0.5 to 1 cc. In 1932 a woman missionary who had acquired undulant fever while resident in China was sent to us for treatment. A goat was the source of the fever. Vaccine therapy did not provoke the usual febrile response. She was then given two artificial fever treatments each of five hours' duration, at 105 F., rectal temperature. All evidence of undulant fever promptly disappeared. She returned to her work in China and has remained well since. It would appear that in all of these methods, including the foreign protein method just described, the production of fever artificially is the common denominator. Through correspondence with the collaborators in the experimental work in artificial fever therapy inaugurated by the Kettering Institute I have learned of more than a score of cases of undulant fever which have been treated with artificially induced fever with uniformly favorable results. One might ask how it happens in a disease characterized by sharp febrile reactions that artificial fever therapy would be effective. It would appear that the prolongation of the fever at a relatively high level stimulates immune reactions. It has been our practice to treat such patients at 105 F., rectal temperature for four or five hours at each session at intervals of two to three days. In most cases two or three treatment sessions will suffice. If the production of sustained artificial fever is the important factor in the treatment it seems logical to conclude that those methods which permit the production of fever under relatively safe and controlled conditions would be the methods of choice. The advent of simpler and safer methods for the controlled production of fever by mechanical means when administered by skilled, trained workers provides such a method. The injection of protein or chemical substances provokes less constant febrile responses and occasionally produces untoward reactions. Our present practice is to give a trial course of *Brucella melitensis* (abortus) vaccine therapy (N. N. R.). If it is ineffective we then utilize artificial fever therapy (Kettering-hyperthermia method). After we had reported 148 cases of undulant fever in and about Dayton, Ohio, in ordinance requiring the pasteurization of all milk and dairy products was passed. During the five years since the passage of that ordinance not one case of undulant fever has originated in Dayton, Ohio. In any consideration of the treatment of undulant fever the best treatment is still to prevent the disease by eliminating the sources of infection.

DR. CARL F. ERVIN, Danville, Pa.: Dr. Simpson's remarks are very helpful in this discussion. I agree with him that fever therapy induced by various mechanical means will probably help out in the treatment of a great many cases of undulant fever. Of course the thing I like best is the

11 Hunt H F, Ervin C F and Nide John S Jr Foreign Protein Therapy I Hematologic Changes following the Intravenous Injection of Killed Typhoid and Paratyphoid B Bacilli. *Am J Med Sci* 1939; 149: 100-106.

vaccine is that it is available to every doctor and he can use it himself. I feel sometimes that it is rather a stimulus to a doctor to feel that after all he can do something himself. The remark about prevention is certainly in order. In the city of Wilkes-Barre, Pa. for instance, I understand that there has not been a case of undulant fever as the result of rigid food inspection. It should be carried out in every rural district and city of the country.

DIAGNOSTIC METHODS IN UNDULANT FEVER (BRUCELLOSIS)

WITH RESULTS OF A SURVEY OF 8124 PERSONS

S E GOULD, M D

ELOISE, MICH
AND

I F HUDDLESON, P U D

EAST LANSING, MICH

The purposes of this paper are (a) to describe briefly the performance and interpretation of the laboratory methods which at present are believed to be most useful in the diagnosis of undulant fever (brucellosis) and (b) to report some of the results of a survey of the incidence of brucellosis in a large county hospital.

LABORATORY METHODS

The laboratory methods which are regarded as most useful are (1) the brucellergen intradermal test, (2) the

opsonic (opsonocytophagic) test (3) the rapid agglutination test and (4) culture (isolation) of *Brucella*.¹

1 The brucellergen test is performed by injecting 0.1 cc of a suspensoid of nucleoprotein (1:2,000) isolated from *Brucella* cells intradermally on the forearm and is read after forty-eight hours (fig 1).

2 The brucella opsonic test is performed by incubating a mixture of a live forty-eight hour culture of *Brucella abortus* and the patient's citrated blood in a water bath at 37 C for thirty minutes. The mixture consists of 0.1 cc of a saline sus-

cent citrate (5 cc of blood added to 0.2 cc of 20 per cent sodium citrate in saline solution). A smear of the mixture is then made on a glass slide, rapidly dried with an electric fan and treated with 0.5 cc of Hasting's stain for thirty seconds, after which 1 cc of distilled water having a pH of 6.4 is added for ten minutes. Twenty-five polymorphonuclear leukocytes are examined and their opsonic power classified according to the number of brucella organisms counted within each cell, as follows: negative, no phagocytized bacteria; slight, from 1 to 20; moderate, from 21 to 40; and marked over 40 (fig 2).

3 The rapid agglutination test is done on a glass plate that is ruled off into inch squares and rests on a dark field illumination box. In each of five squares the

Fig 1—Positive brucellergen test. Note extensive areas of edema.

pension of organisms having a turbidity of 6 mm, as measured by the Gates apparatus, and 0.1 cc of the patient's citrated blood having a dilution of 0.8 per

Fig 2—Brucella opsonic test showing polymorphonuclear leukocyte with negative slight moderate and marked phagocytosis of *Brucella* organisms.

following respective amounts of patient's serum are placed: 0.08 cc, 0.04 cc, 0.02 cc, 0.01 cc and 0.004 cc. A standardized dropper being used, 1 drop of rapid antigen is added to each amount of serum, to form respective serum concentrations of 1:25, 1:50, 1:100, 1:200 and 1:500. The contents of each of the five squares are then thoroughly mixed with a clean toothpick, the operator proceeding in reverse order from the 1:500 to the 1:25 serum concentration. The glass plate is removed from the box, tilted backward and forward slowly for about two minutes and then replaced on the box. The light is now turned on and the results read (fig 3).

4 Culture (isolation) of *Brucella* is done as follows: (a) In taking a blood culture, 10 cc of blood is added to 10 cc of sterile 4 per cent sodium citrate in saline solution and incubated at 37 C for twenty days in a jar in which 10 per cent of the air has been displaced by carbon dioxide (fig 4). The uncoagulated whole blood serves as a highly satisfactory medium for the isolation of *Brucella* while the final concentration of 2 per cent sodium citrate serves to retard the action of opsonins if they are present in the blood. At four day intervals the jar is opened and 0.5 cc of blood-citrate

The authors were given assistance by Dr. Morris Raskin. Work done under a grant from the Horace H. Rackham and Mary A. Rackham Fund, Ann Arbor, Mich.

1 Huddlestone, I. F. *Brucella Infections in Animals and Man*. New York: Commonwealth Fund, 1934. Heller, A. E., Pharris, C. R., and Grub, W. H. *Diagnosis of Undulant Fever*. J. A. M. A. 107: 1369 (Oct. 24) 1936.

mixture is removed and inoculated on a liver agar slant.² The freshly inoculated agar slant is also incubated in the 10 per cent carbon dioxide atmosphere. At each four day interval, all culture tubes are examined for growth (fig. 5).

(b) Specimens of urine, stool, bile, spinal fluid or other infective materials are prepared for culture according to standard methods. Such material is inoculated on plates of liver agar containing gentian violet in a concentration of 1:200,000. One half of the plates are incubated aerobically for ten days, the other half are placed in a container having a 10 per cent carbon dioxide atmosphere and incubated at 37 C for three days.

INTERPRETATION OF RESULTS

1 The brucellergin test is negative if erythema alone is present. A negative test will usually rule out

almost always show little or no phagocytosis. A subject reacting positively to the intradermal test is classified as infected when less than 40 per cent of his polymorphonuclear leukocytes show marked phagocytosis.

TABLE 2—Classification of Positive Brucellergin Reactions Based on Opsonic Tests

Infected Immune	Number	Percent
	229 84	5 100

and as infected but with questionable immunity if from 40 to 60 per cent of his polymorphonuclears show marked phagocytosis. A subject reacting to the intradermal test is classified as immune when 60 per cent

Fig. 3—Killed agglutination test. Note complete agglutination in serum dilutions of 1:500 and 1:100.

brucellosis. The brucellergin test is positive if in addition to an area of redness there is also edema or induration which measures from 0.5 to 7.5 cm or more in diameter. A positive test is specific for sensitization.

TABLE 1—Results of Brucellergin Intradermal Tests on Various Groups, Eloise Hospital, 1935-1936

Group	Number of Tests	Number Positive	Percentage Positive
Hospitalized patient	612	31	5.1
Indigent persons	369	29	7.9
Indigent food handler	49	9	18.4
Employees	—	10	100
Mental patient	4	0	0
All group	1024	845	82.5

to Brucella and is due to past or present infection. It does not, however, indicate the patient's immune status, which may then be determined by the opsonic test.

2 The brucellergin test is a nonphagocytic test in a subject reacting to the intradermal test will

or more of his polymorphonuclear leukocytes show marked phagocytosis of Brucella organisms.

3 A negative agglutination test does not rule out brucellosis. A positive agglutination test consists of complete agglutination in a titer of over 1:25.

4 A positive culture may be found for active infection or for carriers of the disease.

RESULTS OF SURVEY AT FLOISE HOSPITAL

An unusual opportunity to study the incidence of Brucella infection presented itself at Eloise Hospital and Infirmary, whose milk supply was partly infected with Brucella. This public institution of Wayne County (in which the city of Detroit is located) has three divisions: a general hospital (William J. Seymour Hospital), an infirmary for homeless indigents and a mental hospital. All persons in the institution were first tested intradermally with brucellergin.

Table 1 shows the number and percentage of positive reactions among the following groups: hospitalized patients, indigent persons, indigent food handler, employees and mental patients. Among 1024 persons tested, 845 or 82.5 per cent showed positive reactions.

(Continued on next page)

largin reactions The incidence roughly paralleled the average length of stay of the various groups in the institution The incidence was lowest among the hospitalized group (6.2 per cent), whose average stay was the shortest, and greatest among the mental patients (15.4 per cent) whose average stay was the longest

Fig. 4—Apparatus used to produce a 10 per cent carbon dioxide atmosphere for culture of *Brucella*

The 845 persons with positive brucellergin reactions were then classified by means of the *Brucella* opsonic test as infected or immune In 623, or 73.7 per cent the polymorphonuclear leukocytes showed absent slight

The positive brucellergin reactions were accurately measured in all cases and were classified into three groups, as follows those measuring from 0.5 to 2.5 cm in diameter, those measuring from 2.5 to 7.5 cm in diameter and those measuring over 7.5 cm in diameter The size of the intradermal reactions showed little or no relation to the status of *Brucella* infection or immunity (table 6) The percentage of reactions over 7.5 cm in diameter was only slightly greater among the immune persons (30.2 per cent) than among those infected (22 per cent)

TABLE 4—Comparison of Brucellergin and Agglutination Tests

Reaction	Brucellergin	Agglutination	Percentage Agreement
Negative	725	794	89.9
Positive	845	111	13.1

TABLE 5—Agglutination Titers in *Brucella* Infected and Immune Groups

Group	Number	0 to 1:25					Over 1:25	
		0 to 1:25	1:50	1:100	1:500		Number	Percentage
Infected	623	590	11	13	9		33	5.3
Immune	222	144	42	24	12		78	39.6
Positive brucellergin reaction	845	734	53	37	21		111	13.1

Cultures of the blood were made for all 845 individuals with positive brucellergin reaction and of the urine for 370 infected persons The *Brucella* organism was isolated from the blood in four instances of active infection *Brucella abortus* once and *Brucella suis* three times In addition *Brucella suis* was isolated from the urine of one carrier and from the urine and the

	Intradermal Tests	Positive		Infected		Immune	
		Number	Percentage	Number	Percentage	Number	Percentage
Male	5401	525	9.1	422	7.3	106	1.8
Female	2323	317	13.6	201	8.6	116	5.0
Total	8124	845	10.3	623	7.7	222	2.7

or moderate phagocytosis of *Brucella* organisms, and the individuals were classified as infected The remaining 222, or 26.3 per cent showed marked opsonic power and were classified as immune (tables 2 and 3)

Seven hundred and twenty-five persons with negative brucellergin reactions were tested by means of the rapid agglutination method Only one showed a significant serum agglutination titer (over 1:25) Among 845 subjects with positive brucellergin tests 111, or 13.1 per cent, showed a significant serum agglutination titer (table 4) Of the 623 infected persons, thirty-three, or 5.3 per cent, gave a positive agglutination test Of the 222 immune persons, seventy-eight, or 39.6 per cent gave positive agglutination tests (table 5)

stool of a second carrier The *Brucella suis* infections were probably not contracted through the milk used in the institution

The brucellergin, opsonic and agglutination tests were repeated after five months on ninety-nine persons with negative tests, 103 infected persons and eighty-four immune persons The comparison of the *Brucella* status of the subjects in these groups after the five

months interval is shown in table 7. The size of the brucellergin reactions and the results of the opsonic and agglutination tests showed remarkably close similarity to those of the first tests.

The milk used in the institution was unpasteurized and was obtained partly from a milking herd of eight-five cows, nine of which were found to be eliminating

TABLE 6—Size of Brucellergin Intradermal Reactions in Brucella Infected and Immune Groups

Group	Number	0 to 2.5 Cm		2.5 to 7.5 Cm		Over 7.5 Cm	
		Number	Percentage	Number	Percentage	Number	Percentage
Infected	623	196	31.5	260	41.5	137	22.0
Immune	221	43	20.0	110	49.5	67	30.2
Total reactions	845	241	28.5	400	47.3	204	24.2

Brucella abortus in their milk and partly from five other herds whose milk was free from *Brucella abortus*. The incidence of infection among the various hospital groups as judged by the intradermal tests appeared to vary in proportion with the average length of stay in the institution. Table 4 shows clearly that the brucellergin reaction is much more sensitive than the agglutination test in the detection of *Brucella* infections and that the agglutination test is positive in only a small percentage of cases of infection. It would therefore seem that the agglutination test should be used as a confirmatory test rather than be relied on for diagnosis. While a positive agglutination test is of definite value, a negative agglutination test cannot be considered to rule out the presence of brucellosis.

The results of the check of the various tests after five months among the groups of negative reactors, infected subjects and immune persons showed remarkable correspondence for most of the methods. Of the ninety-nine negative reactors, forty-six males and fifty-three females, nine females had a positive reaction and five were classified as infected and four as immune. None of the males were infected. This was taken to mean that the new infections were being produced by infected milk or more likely by means of carriers among the women.

SUMMARY

1. The brucellergin test is the most sensitive test in the diagnosis of brucellosis. If the test is negative, brucellosis will usually be ruled out.

TABLE 7—Results of Brucellergin and Opsonic Tests on Vegetative Reactors and Infected and Immune Persons After Five Months

2. If the opsonic and the opsonic test should then be performed to determine whether infection or immunity is present.

3. A negative brucellergin test does not rule out *Brucella* infection. The agglutination test is diagnostic only in a few cases and gives no information as to the status of the subject.

4. The results of the various tests after five months in the

ABSTRACT OF DISCUSSION

DR I. FOREST HUDDLESON, East Lansing, Mich., in hearing the results of the survey at the Eloise Hospital presented by Dr. Gould, the question arises as to what were justified in classifying such a large number of individuals showing positive allergic reactions as infected. The classification is based on published and unpublished data which have been obtained in cases of undulant fever that yielded positive cultures from the blood, stools or urine. We shall continue to adhere to this classification until some one following the technique shows that the classification is erroneous. The usefulness of this system of tests will depend on how they are performed and interpreted. In the case of the intradermal test with brucellergin, the time interval of reading the test is important. If the result of the test is read under forty-eight hours, it is likely to be misinterpreted as about 50 per cent of the allergic individuals show an intense erythematous reaction at the twenty-fourth hour. Such a reaction may be mistaken for a specific one. The accuracy of the results of the phagocytic test will depend on the adherence to the prescribed technique. The selection of the proper culture for the test is highly important. Certain strains are phagocytized by cells in normal blood as well as in immune blood. The type of reagents and concentration of the reagents used in making the test should be selected very carefully. We do not wish to take the position that the phagocytic test or allergic test cannot be improved. Before one attempts to change the system of tests for diagnosis of undulant fever, it is hoped that a large number of comparative tests will be made before the present system is discarded.

PULMONARY ASBESTOSIS

IV. THE ASBESTOS BODY AND SIMILAR OBJECTS IN THE LUNG

KENNETH M. LYNCH, M.D.
CHARLESTON, S. C.

One of the conspicuous and interesting features of the pulmonary condition resulting from the inhalation of asbestos dust by miners and mill workers in this material is the occurrence of certain curious bodies in the lungs and peribronchial lymph nodes and frequently in the sputum.

These objects have been sufficiently described,¹ but it is relevant here to review briefly their characteristics. They measure from about 10 to more than 100 microns in length and from about 1 to 12 microns in thickness and are composed of a central translucent fiber or needle crystal, the asbestos crystal, with an enveloping shiny golden or brownish substance constituting various architectural figures. The whole object may be a rod with smooth blunt ends or, more often, with one or both extremities in a single rounded knob or a clump of such knobs, reminding one of the fruit body of *Aspergillus*. Frequently the shaft is a series of rounded beads or disks strung closely along the central filament. Again the object may be of the shape of a club, often with one knobbed end or it may be a long slender filament. Spherical forms of various sizes are also seen. Characteristically these bodies give a prussian blue reaction for iron.

McDonald² advanced the hypothesis that the asbestos body is a particle of asbestos fiber in the process of alteration and absorption by hydrolysis with the silicate passing into a colloidal state and a gel.

From the Department of Pathology, Medical College of the South Carolina.

Read before the Section on Pathology and Physiology at the Eighth Annual Session of the American Medical Association, City of New York, June 11, 1937.

¹ McDonald, Stuart. Histology of Pulmonary Asbestos Bodies in Sputum and Lung. J. A. M. A. 107: 159 (A) (1937).

IN THE LUNGS

These bodies may be found in the lungs of asbestos workers, within the bronchioles, the alveoli near about and the interlobular, peribronchial and subpleural tissues along the lymphatic route. They occur also in peribronchial lymph nodes, within sinus walls and

Fig 1—Asbestos bodies in peribronchial lymph node reduced from a photomicrograph with a magnification of 1000 diameters

embedded in fibrosed areas. Here they are usually of the shorter lengths, although some may be surprisingly long considering their route of collection through small lymphatic channels. I have seen them within veins in the lungs, where they may have been dragged in the course of sectioning the tissue, and at least one typical form was found embedded in the splenic pulp. Stewart, Bucher and Coleman² have reported finding them also in the spleen.

Characteristically they are limited to the bronchial tract, the adjacent pulmonary alveoli, the peribronchial connective tissues and the peribronchial lymph nodes.

EFFECTS

In the alveoli they are usually associated with or enclosed by phagocytes, mononuclear or multinuclear, some large foreign body giant cells occurring massed about those of large size. This may be the only cellular reaction to their presence. The following case illustrates this fact.

CASE 1—A Negro, aged 35, whose death was due to arterio sclerosis and pontine hemorrhage, had worked in the carding room of an asbestos factory for a total of five years during an elapsed period of seven years, beginning fifteen years before his death. During his exposure there was no adequate system of dust disposal in this plant, in fact, it was before the recognition of a potential hazard in the industry and the institution of measures of protection of the workers from the dust.

In spite of an undoubtedly heavy exposure and the length of time during which the bodies remained in the lungs, and although they had become deposited within the interlobular tissue around bronchioles there was no definite fibrosis or other reaction to them only phagocytosis of those remaining in alveoli. The lung generally was normal on gross and histologic examination except for an old puckered scar of the left apex.

It appears therefore, that the presence of this material in abundance and over a long period does

not necessarily result in fibrosis or other apparent damage to the tissue. That is to say, the anatomic disease asbestosis may not be assumed to exist simply because of quantity exposure of such a duration, an assumption apt to be the case under current conception.

Often, however, the asbestos bodies not only incite phagocytosis while within bronchioles and particularly alveoli but enter the tissues and apparently the lymphatics and lodge along the course, tending to stimulate growth of fibrous tissue about them. Thus fibrosis of the course of lymphatic circulation in the lungs and peribronchial lymph nodes is the resulting disease. It is generally accepted by students of the condition that the disease is a diffuse type of fibrosis rather than the nodular form of silicosis proper. Lynch and Smith³ have already reported, however, on the occurrence of nodular fibrosis from asbestos inhalation, and I expect to consider this matter again in a separate report.

IN THE SPUTUM

In addition to the conspicuous presence of asbestos bodies in the area of the lung at autopsy, they may be found in the sputum of asbestos workers, by direct microscopic examination of the wet preparation when in numbers or in the sediment of a strongly alkaline solution of sodium hypochlorite or 10 per cent sodium hydrate-digested sputum, even when few.

According to my experience, the presence of these objects in the sputum indicates only inhalation of asbestos dust of sufficient duration for them to be formed. It is apparently possible to find them under conditions probably not conducive to disease. On the other hand, they may not be found even when the lungs are extremely disabled by fibrosis and the bodies are within the bronchioles and alveoli in large numbers.

Fig 2—Deteriorating asbestos bodies in a case of asbesto-silicosis reduced from a photomicrograph with a magnification of 1000 diameters

I have found them in the sputum of an engine room worker at an asbestos plant whose exposure to the dust was not material and who exhibited no evidence of pulmonary abnormality. On the other hand, in three

³ Lynch H. M. and Smith W. A. Pulmonary Asbestosis. II. Including the Report of a Pure Case. Am. Rev. Tuberc. 23: 643 (June) 1931. Pulmonary Asbestosis. III. Carcinoma of Lung in Asbesto-Silicosis. Am. J. Cancer 24: 56 (May) 1935.

cases of long standing extreme fibrosis of the lung, in which many bodies were observed in the lung at autopsy, they failed to appear in examinations by the concentration method of a number of specimens of sputum. Apparently in the fixed state of the lung, with dilatation of bronchioles and alveoli, in extreme fibrosis, these bodies may not be expelled to the exterior.

Fig 3 (case 4)—Asbestos like bodies in lung of cotton compress worker reduced from a photomicrograph with a magnification of 860 diameters

Their presence in numbers in sputum indicates material exposure at a comparatively recent time but without sufficient disability to interfere with the normal course of expulsion of dusts. It does not indicate a grade of asbestosis proportionate to the numbers of the bodies. That is to say, their absence from the sputum of asbestos workers may be consistent with advanced asbestosis, while their presence does not necessarily mean actual pulmonary damage.

ALTERATION

How long these bodies may remain intact and of characteristic form and color within phagocytes and

Fig 4—Asbestos like bodies in lung, reduced from a photomicrograph with a magnification of 860 diameters

within living cellular tissues is unknown. Their tenure of residence is long and may be looked on as practically permanent from their preservation after many years. However it appears that they may undergo the changes of dissolution and may possibly disappear. In fact the beaded forms are looked on by some authorities as weathered forms.

Besides such changes which may indicate deterioration, there occur in old deposits bodies of similar form usually of the smaller clubbed types but not of the characteristic golden or brown color. Instead they take the hematoxylin in routine hematoxylin and eosin staining of microscopic sections. I have seen these forms in fair numbers within old hyaline fibrous areas in association with typical brown bodies in surrounding tissues. These bodies must have been in situ for a long time. Further, I have encountered like hematoxylin-staining bodies within old caseous areas of tuberculosis associated with asbestosis. I take these bodies on the basis of their morphology to be altered asbestos bodies, not only changed in substance but also decreased in size. As to the question of their distribution, in the depths of some old fibrous areas and within some old necrotic associated tuberculosis lesions I have failed to find any, although to judge by their numbers in similar locations elsewhere they must have been present at some time.

Fig 5—Asbestos like bodies in lung in dust deposit in a patient with heart failure reduced from a photomicrograph with a magnification of 400 diameters

OTHER DUST BODIES

After the discovery of the asbestos body the presence of such brownish objects within the lung came to signify practically a previous exposure to asbestos dust. This idea has been altered by the finding of similar bodies when no such exposure had occurred. Tylecote and Dunn,⁴ Cooke⁵ and others have called attention to the occurrence of dust particles with brown coating in the lungs of workers in coal.

I have observed a considerable number of autopsies following death from a variety of diseases, in which the lungs contained brown bodies to be compared to asbestos bodies. The following cases are illustrative.

CASE 2—A Negro, aged 32, who had been a coal miner most of his working life and had not worked with asbestos at any time, died of chronic pulmonary tuberculosis. In his lungs, besides large deposits of granular and splinter material in fibrosed areas about lobular vessels and within giant phagocytes in certain alveoli, many brown bodies not unlike the smaller forms of asbestos.

⁴ Tylecote F F and Dunn J S. Case of Vascular Disease in the Lungs of a Coal Miner Who Had Never Worked with Asbestos. *Lancet* 2, 632 (Sept 19) 1931.
⁵ Cooke W E. Silico-Anthraxosis. *Internat. J. Tuberc. Dis.* 1, 1, 1 (April 1) 1933.

bodies were observed. These were single spherical forms globular and disk shaped forms in rows or chains and club shaped bodies and rods, some with one or both ends knobbed. Often the centrum could be made out as a black granule or, in the larger bodies, a black splinter, but the brown coating was like that of the asbestos body.

CASE 3—A Negro housemaid who had never worked in asbestos died of malignant myoma of the uterus. Her lungs

Fig 6—Asbestos like bodies in lung reduced from a photomicrograph with a magnification of 860 diameters

contained a black amorphous material similar to that in the lungs of the coal shute worker, although less in quantity and numerous brown bodies of like kind and of similar distribution associated with a state of emphysema and chronic bronchitis but with no definite related fibrosis.

CASE 4—A Negro, aged 45, who had worked virtually all his working life (20 years or more) in a cotton compress and not at all in asbestos, died of arteriosclerosis and pontine hemorrhage. His lungs contained large numbers of golden brown bodies, some closely resembling asbestos bodies. They were of the smaller sizes and of various shapes, as in the previous cases cited, and were accompanied by black dust. They did not show the black centrum but rather a central body of translucent appearance, fiber-like. In the alveoli there were large numbers of mononuclear phagocytes containing fine dust but no brown bodies. No material fibrosis was associated with the deposits.

Similar brown bodies have been observed in the lungs of a considerable number of subjects who died of heart failure, particularly rheumatism (fig 5) and arteriosclerosis (fig 6).

Generally the number of bodies found was small, but in some instances they were quite conspicuous. In fact, in some cases a diagnosis of asbestosis was made on routine examination and stood until investigation satisfactorily showed no such occupational exposure.

It has come definitely to my mind that chronic congestion of the lungs may play a part in the formation of some of these bodies, at least that congestion may augment or favor the formation of the enveloping substance. In this connection, a close study of the brown iron-bearing granules in the mononuclear cells in alveoli in cases of congestive heart failure (heart failure cells) will disclose that many of them contain a black granule centrum.

The bodies here described have generally been more conspicuous in cases of rheumatic heart disease. They have always been associated with black particulate matter and except in the case of the cotton compress

worker a black centrum could be seen. Only the small round forms occurred commonly in phagocytes in alveoli. The larger forms, rods, clubs and chains, were found mainly within the tissues of the interlobular framework. They gave the prussian blue reaction for iron, as does the asbestos body. Their iron content and their seeming common connection with pulmonary congestion and the local liberation of blood iron again raises the question as to whether the iron of the asbestos body may not be so related, at least in part and whether congestion may at least favor the production of all such bodies.

In connection with this question it may be recalled that the asbestos body does not always form when asbestos dust comes to lie in the lungs or in other tissue even for periods usually sufficient to produce it. Schuster⁶ reported on the occurrence of asbestosis in a dog, in which only naked asbestos fiber was found, with no brown envelop produced, while Gardner and Cummings⁷ found that the asbestos fiber remained uncoated in experimental asbestosis of the rabbit.

Usually, I am confident, such deposits in the lungs may be distinguished from asbestos bodies, particularly because of the larger sizes and the translucent needle centrum of the latter, but the form is often similar and the formation of the brown smooth coating must be by the same or a similar process.

SILICA BODIES

The state of the dust particles to be found in cases of silicosis proper seems to warrant special consideration in a study of the deposits associated with dust disease. In my series silicosis is scant and therefore my observation not extensive. However, in this small amount of material, including a case of advanced typical nodular fibrosis attending extreme accumulation of dust in the lung with much deposit of hemosiderin,

Fig 7—Silica bodies resembling asbestos bodies reduced from a photomicrograph with a magnification of 375 diameters

the formation of an enveloping substance about the dust particles similar in color and appearance to that about asbestos and the other particulate matter here discussed was striking.

6 Schuster N H Pulmonary Asbestosis in a Dog *J Path & Bact* 34 751 (Nov) 1931
7 Gardner L U and Cummings D E Studies on Experimental Pneumonokoniosis VI Inhalation of Asbestos Dust Its Effect upon Primary Tuberculous Infection *J Indust Hyg* 13 65 (Feb) 1931

This formation is encountered wherever the dust is found in alveoli, associated particularly with hemosiderin granules and occurring in mononuclear phagocytes, in the interlobular tissues and in the hyaline fibrous nodules. The form of the body is dependent on the size and the shape of the dust particle of course, and none of the large bodies occurring in asbestosis are to be seen. However, the small forms seen in asbestosis are well simulated. The enveloping substance is shiny, usually less noticeable than that of the asbestos body and a lighter golden as a rule but sometimes a comparable brown.

The most common body is rounded, sometimes truly spherical, with a pale golden envelop on a black granule. When the dust particle is elongated the whole body is shaped like a rod, club or needle. Some bodies are rough and irregular, when the centrum of the dust particle is irregular, rhomboidal or chipped, but the surface of the envelop is always smooth.

The formation of these silica bodies in true silicosis seems to be just as much a part of the process concerned as in the probably related state of asbestosis.

It appears possible that other fiber or crystalline dusts not yet particularly studied may produce similar bodies and also that confusion of some consequence may result from failure to realize that asbestos bodies may be simulated by other deposits in the lung.

As to the nature of all of these objects, it appears that they are formed on a silica base, as is the asbestos body. On that hypothesis the group would become silica bodies, of which the asbestos body is a member.

16 Lucas Street

ABSTRACT OF DISCUSSION

DR. HENRY C. SWEANY, Chicago. The asbestos fiber is from 100 to 200 microns in length on an average with occasional shorter pieces. Owing to its length it has great difficulty in following the lymphatic channels. It is usually stopped in the smaller bronchioles and from there works its way through the bronchial wall and but rarely proceeds much farther. Therefore there is not the tendency to enlargement of the hilar lymph nodes seen in silicosis. The fibrosis has a tendency to be more of a linear and stringy type and does not tend to form into the regular ball of twine whorls seen in silicosis. One of the similarities between silicosis and asbestosis is the individual difference that Dr. Lynch has mentioned between one patient and another. The disease may develop in one person much more readily than in another yet some may be exposed for a long number of years without showing much detriment. It is a most important and timely observation relative to the presence or absence of these asbestos bodies. He has pointed out wisely that sometimes they may be present when the patient has no asbestosis and that they may be absent with an asbestosis. It isn't so simple as to take a little sputum, make a smear and find these golden yellow bodies. It is really quite difficult to establish a definite diagnosis of the disease. I should like to ask Dr. Lynch whether he has made any observations on the character of this yellow pigment. The latest reports that I have read on the subject by Gardner, Glove, Burger and Merewether say that the presence of the golden yellow pigment is thought to be due more than anything else to the presence of iron in the fibers. Asbestos is an alkali magnesium silicate with some calcium and some iron in various proportions but the presence of iron seems necessary in order to give the golden color. The disintegration process that goes on causes the fibers to assume the various club shapes and ultimately they are entirely resorbed and disappear as Dr. Lynch has shown. I believe that silicosis in which there is pure silicon dioxide is different. I don't recall having seen any of these golden yellow bodies in silicosis and I have examined a large number of specimens. I believe that the iron or some other substance in the asbestos fiber is more responsible for the color and therefore one should not expect to find it in silicosis. It

is pertinent that these old chronic cases with passive congestion and accumulation of iron may also show golden yellow bodies, as I have seen them in other diseases.

DR. KENNETH M. LYNCH, Charleston, S. C. In reference to the occurrence of objects in the spleen which may be taken for these bodies, they have been reported in that location. I have seen there in a few cases objects that I would call asbestos bodies, but I really did not know whether they might be other bodies coated with iron in the congested state of the spleen. I presume that the iron has something to do with the formation of this smooth brown coat about the asbestos fiber in the lung. However, it doesn't always form. In the lungs of a rabbit in experimental asbestosis, Gardner observed that the asbestos fiber remained naked and did not become coated with this brown material. Shuster has reported that in asbestosis in a dog the fiber was naked, without any coating. So far as I know, the material is considered a colloid developed from decomposition of the silicate the asbestos fiber by a process of hydrolysis, probably at the beginning of deterioration and decomposition of the material, in connection with the lung tissue. I cannot say much about the occurrence of smaller objects of similar kind in silicosis because I see very little silicosis. I think we have got to break down pneumoconiosis into consideration of the effects of special kinds of dusts; that is, the material making up the dust rather than considering silicosis as a whole. It is not unlikely that there are other dusts that have not yet been studied which may come in for some part in pneumoconiosis. I have studied the dust of fertilizer factories, in the lungs of workers without discovering any change in the dust at all, or any influence on the lung. Dr. Sweany is correct about the opportunity for collection of these larger objects through the lymphatic circulation of the lung as compared to the smaller granules of silicosis. They collect more along the bronchial route, that is around the bronchi but they do occur in the lymph nodes of the hilus to a surprising extent. When one considers the size of them and how these rather angular particles must be transported through the lymphatics to arrive finally in the numbers I have seen in some lymph nodes, it is astonishing. I believe, however, that more of the deteriorated forms are seen in lymph nodes than in the lung tissue.

Clinical Notes, Suggestions and New Instruments

BURNS FROM IGNITION OF CELLULOID COMBS

HOWARD FOX, M.D., NEW YORK

The danger of severe burns from ignition of celluloid combs is not generally recognized by the public. Such burns have usually occurred while the so-called water wave was being made in the hair. In this beautifying process the scalp is first shampooed or simply moistened, the combs are placed in suitable position and the hair is then allowed to dry by room temperature or by artificial heat. It is during the drying process by artificial heat that disastrous results may take place if the heating apparatus is too close to the hair.

Six cases of severe burns from the ignition of celluloid combs have come to my attention in the last few years. In all of them the scalp was injured by third degree burns causing scars and permanent loss of hair. All except one of the patients also had burns on other parts of the body. Two of them were severely injured when the clothing was set on fire.

In one of these cases the accident occurred in a beauty parlor, in the others when the victims were at home. The source of heat used for drying the hair in these cases was either an electric lamp, a gas heater or a stove.

REPORT OF CASES

CASE 1 (Oct. 14, 1927).—Mrs. M., aged 40, while visiting friends in a German city attempted to produce a water wave using twenty or more celluloid combs which she had brought from the United States. She then dried her hair near a gas lamp stove. Ignition of the combs produced a third degree burn of almost the entire vertex and upper occipital region. The burns healed in ten weeks. When seen in the hospital

after the lesions had healed, the affected part of the scalp was red, atrophic and bald. There was also some scarring of the left side of the forehead and left ear as a result of the burns.

CASE 2 (Oct 17, 1927)—Miss O, aged 32 while having a water wave at a beauty parlor suffered a third degree burn 3 by 4 inches (7.6 by 10 cm) on the parieto occipital region. One or more of the combs ignited from the heat of a large lamp. On putting her hand to her scalp she also sustained second degree burns of her palm and fingers. The lesion of the scalp was healing at the end of three weeks when the patient was last seen.

CASE 3 (March 31, 1930)—Miss P, aged 25, while giving herself a water wave three years previously, used four celluloid combs. In drying her hair she sat in front of a gas heater. The combs ignited and the flames were extinguished by her mother, who threw a blanket over the patient's head. The burned area required four months to heal. At the time of examination she presented a completely bald atrophic area about 2 inches in circumference on the frontoparietal region.

Fig 1 (case 2)—Third degree burns of scalp

CASE 4 (July 17 1931)—Miss X, aged 18 while waving her hair in December 1929 used six celluloid combs and dried the hair with a small electric hand lamp. As a result of ignition of the combs and clothing she sustained burns of the scalp face ears neck and both shoulders and right hand. The burns varied from second to third degree and required subsequent skin grafting on the scalp face and shoulders. As a result of her injury she was confined to bed at home and in a hospital for three months. Examination showed several bald atrophic areas of the scalp the largest being 2½ inches (6.3 kg) in the longest dimension. There was some loss of tissue of the right helix forehead nose upper part of the cheek and right eyebrow. There were also slightly elevated scars on the shoulder and smooth scars on the neck on the supraclavicular region and on several fingers.

CASE 5 (July 15 1931)—Miss H, aged 18 while waving her hair with celluloid combs in August 1930 used an electric lamp for drying purposes. The combs ignited burning her clothing and producing severe burns which confined her to bed for six weeks. Examination showed four areas of baldness and scarring in the left parietal region the largest area being 1½ inches in length. There were also keloidal scars in the right axilla the mastoid and supraclavicular regions and the right elbow.

CASE 6 (June 24, 1936)—Miss M D, aged 22, a patient of Dr Maurice J Costello, gave herself a water wave Oct 10 1935, with twelve celluloid combs. While using a heat lamp for drying the hair she heard an explosive sound, followed by burning of her hair and some of her clothing. She sustained third degree burns of the scalp hands and left knee which required hospitalization for two months. Some of the burns did not heal completely until the end of one year. She now presents an area of permanent baldness the size of a palm and scarring in the right parietal region. There is a smaller scar on the right side of the forehead and there are also scars on the hand and right knee. When performing the water wave the patient thought she was using 'india rubber' combs. However they burned suddenly in an explosive manner, and one of them submitted later to Dr Costello proved to be made of celluloid and not of rubber.

Fig 2 (case 5)—Scars from burns due to ignition of celluloid combs and clothing. The patient was confined to bed for six weeks.

COMMENT

Combs for the production of water waves are frequently made of celluloid and apparently owe their popularity to the fact that they are light in weight, flexible and cheap. They are sold in large numbers at some department stores and at

Fig 3 (case 6)—Scar from burn of scalp which required a year to heal. The patient remained in the hospital for two months.

practically all five and ten cent stores. All celluloid combs are extremely dangerous to use in the hair if artificial heat is applied for drying purposes. Celluloid combs burn almost instantaneously and noiselessly and set fire to the hair before the victim realizes what has happened.

Samples of different varieties of combs for making water waves were obtained from twenty different stores in the metropolitan district of New York. The majority of the combs were made of celluloid, some were made of hard rubber and a few were of metal.

Metal combs are naturally safe but they are not widely used probably because they are rather heavy and stiff and tend to scratch the scalp. Hard rubber combs are more popular, though most of them are inflammable. They are, however, somewhat less dangerous than celluloid combs, since they do not burn as rapidly and they are apt to give a crackling sound of warning on ignition. One type of comb was advertised as being "noninflammable." This did not prove to be true, as a sample that was purchased burned readily. This was a metal comb coated with lacquer.

A warning of the danger of ignition of inflammable combs is often given the purchaser, but it is apparently seldom heeded. Captions such as "inflammable, avoid heat" and the like are often printed on the carton containing the combs for sale or in some cases are stamped on the individual comb. On some there is no warning whatever. On two occasions the saleswoman stated that certain combs were not at all inflammable, though when tested later they burned almost instantaneously when a match was applied to them.

It is hard to understand why a manufacturer or seller of a dangerous article such as celluloid combs should not at least protect himself against possible litigation by suitable warning of fire hazards. My contention is however that even though such a warning is given regarding the inflammability of celluloid combs, they should never be allowed to come in close contact with heat.

SUMMARY AND CONCLUSIONS

1 Six cases of third degree burns followed ignition of celluloid combs, which were used by women for producing "water waves."

2 Celluloid combs should never be used when heat is applied to dry the hair.

140 East Fifty-Fourth Street

PLEURAL ASCITES THE RESULT OF TRAUMATIC RUPTURE OF THE DIAPHRAGM IN A CASE OF LATENT HEPATIC CIRRHOSIS

SAMUEL GOODMAN MD TULSA OKLA

A careful search of the literature on traumatic rupture of the diaphragm of which there are well over 1,000 cases recorded, fails to show one similar to the following case. The unusual angles presented during the course of the patient's illness provided a most difficult problem in diagnosis.

REPORT OF CASE

History—A man aged 56 an oil producer admitted to St John's Hospital Jan 17 1937, complained of cough shortness of breath, weakness and fever. Three days before admission a temperature of 103 F developed with increasing cough and dyspnea. Dulness was found over the base of the right lung and the breath sounds over the same area were quite distant. The fever abated but the area of dulness increased during the next two days. He was referred to my service at the hospital on the following day.

The patient had been in an automobile accident Dec 9, 1936 and was admitted to another hospital in the city with a fracture of the sternal end of the right clavicle and a fracture of the second and third ribs on the right side near the sternal junction. At that time he was in moderate shock and slightly cyanosed. He had a cough with expectoration of frothy blood and subcutaneous emphysema over the wall of the upper right side of the chest. The temperature was 100.4 F, the pulse was 80 and the respiration rate was 28 and shallow. Examination of the chest at that time showed evidence of collapse of the right lung. The white blood cell count was 10,650 polymorphonuclear leukocytes 82 per cent lymphocytes 14 per cent monocytes 2 per cent eosinophils 2 per cent. The urine showed a trace of albumin with occasional hyaline casts and a few pus cells. The Kahn reaction of the blood was negative. During his stay in the hospital the cyanosis

gradually disappeared, but he continued to cough and had a temperature ranging from 98 to 100 F. He was discharged December 18. He was seen several times at his hotel and continued to improve, although he still had slight elevations of temperature, cough and dyspnea on moderate exertion.

His past history was irrelevant except for the fact that he drank alcoholic liquors freely and that he had syphilis which had been treated intermittently since 1929. He had had considerable antisyphilitic treatment, including a course of malarial treatment in 1931 at which time it was thought that there was some evidence of dementia paralytica. He continued, however, to carry on a successful business until the date of the accident. There was no history of gastro-intestinal symptoms or of systemic disturbances.

Examination—The patient was fairly well nourished and developed with slight dyspnea, but apparently he was in no great discomfort. Examination relative to the head and neck was negative except that the mouth was edentulous, the tonsils were large but not septic, and there was some enlargement of the superficial veins on the right side of the neck. The chest was elliptic, the right side being larger than the left. There was a bony deformity of the right clavicle at the sternoclavicular articulation. No expansion could be detected on the right side, which was absolutely flat on percussion over the apex to the base. Breath sounds were distant throughout the entire right side of the chest. Tactile and vocal fremitus were diminished. The left lung was clear. Examination of the heart showed the point of maximum impulse at the fifth interspace in the left midaxillary line. The sounds were of good quality and the rhythm was regular. The abdomen was scaphoid. There were no masses or muscular tenderness. Some fulness and increased resistance was noted in the upper right quadrant below the costal margin. There were no dilated superficial veins. Neuromuscular examination was negative. There was no edema of the extremities. The genitourinary tract was normal except for a scar 4 mm in diameter on the right side of the glans penis. Rectal examination was negative. The laboratory examination showed hemoglobin 15 per cent, red blood cells 4,200,000, white blood cells 13,000, neutrophils 78 per cent lymphocytes 20 per cent, eosinophils 1 per cent, basophils 1 per cent, Cook-Ponders index 191. The temperature was 99.6 F, pulse 80, respiration rate 22. The Wassermann and Kolmer reactions were two plus; the Kahn reaction was negative and the Kline reaction was two plus. The urine was normal except for a few white blood cells and a specific gravity of 1.030. Roentgenograms of the chest showed a marked opacity of the entire right lung field with displacement of the heart and mediastinum to the left. Jan 18 1937 the right side of the chest was aspirated and 3,000 cc. of a straw colored clear fluid was obtained which had a specific gravity of 1.012 and showed but few cells and no bacteria. Culture was negative. Three days later, 2,400 cc. of the same type of fluid was aspirated. Following this aspiration a succession splash could be obtained and there was amphipneic breathing above the level of the fluid.

Radiologic examination of the chest on the following day showed pneumothorax extending to the apex with the fluid in the interspace and a marked opacity below to the base. The heart was still displaced to the left. Examination January 22 showed evidence of a reaccumulation of fluid which increased gradually the next three days. January 28 5,200 cc. was aspirated. January 30 2,500 cc. of fluid was aspirated. February 1 3,700 cc. of the same type of fluid was aspirated. Roentgenograms of the chest February 2 showed the level of fluid at the third rib anteriorly with pneumothorax above it. February 3, the white blood cells numbered 9,100, neutrophils 88 per cent lymphocytes 12 per cent Cook-Ponders index 211. February 6 the right side of the chest was aspirated and 3,000 cc. of fluid was obtained. An examination of this fluid showed 85 per cent neutrophils 5 per cent eosinophils and 10 per cent other types. Culture was negative. February 8, 650 cc. of the same type of fluid was aspirated. In view of the rapid refilling of the right pleural cavity with fluid it was deemed advisable to determine if possible the cause of this rapid refilling. A total of 20.4 cc. of fluid was aspirated during a period of twenty-one days. February

10, roentgenograms taken both in the supine and in the upright position showed no free iodized oil in the pleural cavity. It did show a marked compression of the right lung with good filling of the left bronchial tree. The upper fluid level in the right side of the chest was at the fourth rib.

Course—During the period from the date of entrance to February 11 the patient was not unusually uncomfortable. The temperature range was from 98 to 101 F. There was moderate discomfort of the chest and some anorexia with increasing loss of weight and increasing weakness. February

Fig 1—Appearance Feb 10 1937 on bilateral injection of iodized oil with patient in supine position. Note compression of right bronchial tree and finger-like opacity in region of right diaphragmatic sulcus. Autopsy proved this to be omentum projected into the pleural cavity.

12 the patient became drowsy, the skin developed an icteric tinge, the abdomen became distended, and an indefinite fluid wave could be obtained. The Wassermann reaction of the spinal fluid was negative. During the ensuing twenty-four hours the patient failed rapidly. February 13, nonprotein nitrogen was 36 mg. The icterus index could not be determined because of hemolysis. Anuria developed and he became comatose and died, apparently of acute liver failure. Autopsy was performed by Dr. I. A. Nelson two hours after death.

Autopsy—The body was well developed but

somewhat emaciated. External examination showed no jaundice in artificial light, no scars were evident. The bones were regular except for some protuberance of the right clavicle at the sternoclavicular junction. The pupils were dilated and equal. Internal examination of the thorax showed the right pleural cavity filled with a straw-colored fluid and all lobes collapsed. The right diaphragm had a perforation about 2 cm in diameter at the dome with a portion of the omentum passing through it. The omentum was adherent to the anterior edge of the perforation but failed to close the opening. The tip of the little finger could pass through the unclosed portion. There were numerous small capillaries both on the diaphragm and on the omentum at the region of the adhesion. About 10 cm of the omentum extended into the pleural cavity. This free portion of omentum was fanlike and when spread over the perforation tended to act as a flap valve. There was an additional valve mechanism formed when the abdominal pull on the omentum brought the smooth free edge of the perforation against the liver. Thus there was a free opening between the peritoneal and the pleural cavity but any tendency for fluids to flow from the pleural cavity into the peritoneal cavity was prevented by either or both valve actions.

The right parietal and visceral pleurae appeared fairly normal. The collapsed lobes of the right lung showed no areas of induration. The left pleura and lung showed no pathologic changes. The pericardial sac contained about 300 cc of straw-colored fluid. The heart weighed about 250 Gm with valves, musculature and coronary arteries normal. The aorta showed a moderate degree of arteriosclerosis. The mediastinum and heart were somewhat deflected to the left but were not fixed.

Examination of the abdominal cavity showed a small amount of free fluid. The omentum was relatively small and directed over the anterior edge of the liver to the dome of the right diaphragm, where it was adherent, as already described. The liver weighed 870 Gm, it was pale with surfaces uniformly nodular with nodules about 1 cm in diameter and the capsule somewhat fibrous. The cut surface of the liver was dry and fairly smooth, with traces of yellowish mottling and a slight granularity. The gallbladder was not distended. It emptied

readily and did not contain any stones. The spleen weighed about 360 Gm. It was a purplish gray. The capsule was smooth, gray and somewhat thickened with a firm consistency. The cut surface was fairly dry. The peritoneum showed numerous delicate but distinct capillaries extending from the cardiac end of the stomach to the spleen. The pancreas weighed about 60 Gm and was firm without tumors, hemorrhages or areas of softening.

The esophagus showed some varicosities. The cardiac end of the stomach showed some congestion. The pylorus appeared edematous. There was freedom from ulceration or tumors. The duodenum, jejunum, ileum, colon sigmoid and rectum appeared normal. The adrenals did not show tumors, hemorrhages, cavitation or abnormalities.

The right kidney weighed 130 Gm and the left kidney 120 Gm. The surfaces were smooth, the capsules stripped easily and the cortex and medulla were distinct. The pelves were moist, smooth and of a pinkish gray. The ureters showed no dilatations or abnormalities. The bladder was empty. The mucosa was velvety and the walls were regular. The prostate showed no enlargement or induration. The brain was not examined.

The anatomic changes found were (a) atrophic cirrhosis of the liver, (b) traumatic perforation of the right diaphragm, (c) hernia of omentum into the right pleural cavity with diaphragmatic adhesion, (d) right hydrothorax, (e) compression collapse of the right lung, (f) esophageal varices, (g) mild gastritis and (h) splenomegaly.

On microscopic examination (a) the heart muscle showed some nuclear anisocytosis and slight fibrous infiltration, (b) the left lung showed some recent bronchiolitis and the right lung marked atelectasis, (c) the kidneys showed cloudy swelling and focal hemorrhagic nephritis, (d) the liver showed lobular atrophy and regeneration with marked interlobular fibrosis. There were some small areas of fatty degeneration and some similar to central necrosis except that the lobular architecture did not conform to the venous distribution.

In a collection series of 1,003 cases of diaphragmatic hernia Hedblom found that 34.9 per cent were of traumatic origin.¹ About 95 per cent of the traumatic hernias occur on the left side.² There are several theories suggested as to the low incidence of traumatic hernias on the right side. It is thought that the liver acts as an effective protection to the right side of the diaphragm and that, owing to the structure of the right side, more resistance is offered to sudden increases in intra-abdominal pressure. As a result of the protection afforded by the liver, hernias on the right side are not as large as those which occur on the left side. About 50 per cent of the right diaphragmatic hernias are located centrally and usually contain only omentum if the opening is small.

Reasoning from the changes found at autopsy, this patient had a latent cirrhosis of the liver. The chest and abdominal injury apparently ruptured the dome of the right diaphragm with a resulting omental hernia, which acted as a flap valve. This allowed free access of fluid from the supracolic basin and effectively prevented fluid from accumulating in the abdominal cavity in any demonstrable quantity. The trauma either contributed to or occurred coincidentally with that critical stage of liver dysfunction during which ascites

Fig 2—Appearance February 10 on bilateral injection of iodized oil with the patient sitting upright. Note upper level of fluid pneumothorax and collapsed lung.

1 Lewis Dean Practice of Surgery Hagerstown Md W F Prior Co Inc 5 18 (chapter 7) 1930
2 Lewis Dean Practice of Surgery 5 20 (chapter 7) 1930

develops. While latent cirrhosis of the liver, often unrecognized during life occurs commonly, the circumstances present in this case successfully masked a condition which ordinarily would be considered in making the diagnosis. At no period, except for forty-eight hours before death, was there any evidence of demonstrable fluid in the abdominal cavity.

Persistent and rapid reaccumulation of serofibrinous fluid in the pleural cavity occurs most commonly in tuberculosis and malignant disease. Since neither one of these could be demonstrated the possibility of bronchial fistula was considered particularly in view of the fact that the right lung would not reexpand. An effort to demonstrate the possibility of a bronchial fistula by injection of iodized oil was without result. The roentgenograms show the difference between the compressed bronchial tree of the right lung and the normal bronchial tree of the left lung. I believe that this case illustrates another, although rare, cause of rapid reaccumulation of fluid in the pleural cavity to be considered in differential diagnosis.

SEVERE DERMATITIS MEDICAMENTOSA FOLLOWING THE ADMINISTRATION OF SULFANILAMIDE

J. OWEN FINNEY, M.D., GADSDEN, ALA.

The initial clinical and experimental report of the use of sulfanilamide (para-amino-benzene-sulfonamide) in this country was by Long and Bliss.¹ Subsequent reports have shown its worth in the treatment of hemolytic streptococcus infection,² meningococcal infection,³ and gonococcal infection,⁴ and one report has been concerned with its apparent efficacy in the treatment of severe gas bacillus infection.⁵

Certain toxic manifestations have been recognized since early in its use. These are dizziness, lassitude, general malaise, cyanosis, sulfhemoglobinemia and fever. Harvey and Janeway⁶ reported three cases of acute hemolytic anemia that developed during the administration of the drug, and all three experienced prompt recovery following blood transfusions. Schwentker and his associates⁷ mention the fact that a morbilliform rash occasionally occurs in patients when sulfanilamide is used in the treatment of streptococcal infections. Hageman⁷ states that such a rash appeared in about one half of his cases that showed a febrile complication following use of the drug. As a rule, all these toxic manifestations have rapidly receded with reduction of the dosage or withdrawal of sulfanilamide.

I have at the time of this writing been unable to find a case reported in which the skin manifestations following the use of sulfanilamide have been of sufficient severity to demand hospitalization. For this reason the case reported herein is of importance.

REPORT OF CASE

History.—I. R., a white man aged 29 married a farmer first seen Aug. 7, 1937, complained chiefly of "skin trouble and itching." He had consulted a physician some two weeks previously who told him that he had an acute recurrence of an old gonorrheal prostatitis associated with a cystitis. He had been given a prescription for some tablets, of which he took four four times daily for one day, three four times daily for two days and two four times daily for eight days. (Communication with his physician revealed that the prescription was for sulfanilamide.) About the sixth or seventh day of treatment he began to notice rather marked itching of the skin of the

face, arms and chest. He attached no significance to it and continued to take the drug. The symptoms increased in severity and on the last day of treatment he noted the appearance of a rash over his face, arms and chest. During the two days previous to admission marked swelling of the face and arms had occurred and the rash had become notable on the back of the buttocks and the dorsum of the feet. He had not been in contact with arsenic to his knowledge and had had no other medicine for some time prior to the use of the sulfanilamide. His past history revealed that he had had measles; he had never had any allergic manifestations. The family and personal histories were irrelevant.

Appearance of patient on second day in hospital. There had been no improvement since admission but the lesions were still quite distinct and the edema had not completely subsided.

The patient was obviously very ill and was immediately admitted to the Holy Name of Jesus Hospital for examination and study.

Physical Examination.—The temperature was 101.6 F, the pulse 120, the respiration rate 20 and the blood pressure 140/90, systolic, 80 diastolic. He was exceptionally well developed and well nourished and was oriented and cooperative though quite uncomfortable. He rubbed various areas of his skin frequently and complained bitterly of generalized itching and of "tightness" of his face. There was a symmetrical maculopapular rash over the body that was most marked on the face, anterior surface of the chest, flexor surface of the arms and extensor surface of the fingers. A similar, though less severe reaction was present over the buttocks, posterior part of the thighs and the dorsum of the feet. The lesions were in some areas discrete while in others they were confluent so as to form large patches. There was an associated edema of the face so well marked to all but close the eyelids, over the chin there was corneal crusts. Edema of the arms was present to a mild degree. The fingers were so swollen that the patient could not make a tight fist. The palms and soles were uninvolved. The mucous membranes were of good color and there were no lesions. There was no local or general glandular enlargement. There was no urethral discharge and the prostate was though mildly boggy was not tender. The remainder of the examination was not remarkable.

A voided specimen of urine was slightly cloudy and had an acid reaction; specific gravity was 1.015, albumin was

plus and sugar was not present. The sediment was loaded with white blood cells and there was an occasional large clump. The hemoglobin was 90 per cent (Sahli), the erythrocyte count was 4,900,000, the leukocytes numbered 11,350 with a differential of 65 per cent polymorphonuclear neutrophils, 29 per cent lymphocytes, 4 per cent eosinophils and 2 per cent basophils. The stool was not notable. The nonprotein nitrogen was 31 mg per hundred cubic centimeters of blood. The fasting blood sugar was 93 mg per hundred cubic centimeters of blood. The blood Wassermann and Kahn reactions were negative. Stained sediment of the urine showed pus cells but no gram negative intracellular or extracellular diplococci. A fixed smear of the prostatic fluid showed pus cells but no organisms. The phenolsulfonphthalein renal function test revealed 83 per cent of the dye in two hours. No determination of the sulfanilamide content of the blood was attempted.

Course.—The patient was placed at rest in bed and given a liquid diet. Fluids were forced to 4,000 cc daily. On admission the lesion so greatly resembled a very early arsenical dermatitis that oatmeal baths were employed at frequent intervals. He obtained such marked symptomatic relief from these baths that they were continued until his discharge from the hospital. No other therapy was given and the symptoms gradually subsided over a period of four days, on the fifth day the patient left the hospital with a normal temperature, the skin was practically clear. Since leaving the hospital he has been seen at frequent intervals and there has been no recurrence of the dermatitis. No attempt has been made to reproduce the condition by giving the patient additional sulfanilamide. The illustration shows the patient on the morning of the second day in the hospital at which time he had already begun to improve.

SUMMARY

In a case of dermatitis medicamentosa following the administration of sulfanilamide (para-amino-benzene sulfonamide) the skin manifestations and general condition were of sufficient severity to demand hospitalization of the patient. Recovery was rapid, complete and uneventful with the employment of palliative measures. No attempt was made to reproduce the picture by repeating sulfanilamide after recovery.

EXFOLIATIVE DERMATITIS FOLLOWING
SULFANILAMIDE

CORDON B. MYERS, M.D., E. C. VONDER HEIDE, M.D., AND
MATTHEW BALCERSKI, M.D., DETROIT

With full doses of sulfanilamide or related compounds, such toxic manifestations as weakness, lassitude, dizziness, anorexia, nausea, slight cyanosis and mild acidosis occur frequently. According to Long and Bliss¹ it is not necessary to discontinue the drug when these symptoms appear. With the development of fever or jaundice not attributable to the infection under treatment, withdrawal of the drug is advised. The only grave complications of sulfanilamide therapy reported to date are one case of sulfhemoglobinemia resulting in death,² three fatal cases of agranulocytosis³ and five cases of acute hemolytic anemia⁴ in which recovery occurred after repeated transfusions.

Morbiliform skin eruptions and hyperpyrexia have been described during the course of sulfanilamide therapy⁵ but no

severe protracted dermatitis has been reported thus far. The following case of exfoliative dermatitis is therefore presented.

REPORT OF CASE

A white man, aged 25, contracted gonorrhea in March 1937. After an unsuccessful trial of urethral irrigations and instillations, sulfanilamide therapy was instituted. He received 75 grains (5 Gm.) orally on June 23 and 50 grains (3.3 Gm.) daily thereafter until July 17. The discharge subsided temporarily early in July, only to return after prostatic massage disappearing again about the middle of July. There were no toxic symptoms whatever until July 17 when he began to notice weakness, lassitude, anorexia, dull aching pain in the epigastrium, giddiness, pain in the eyes, and dryness in the throat and conjunctivae.

Between June 23 and July 17 the patient had been given 1,300 grains (86.6 Gm.) of sulfanilamide. No other medication was administered during this period. The dose of the drug was reduced to 25 grains (1.6 Gm.) July 18, but as the symptoms did not abate it was discontinued July 19. The temperature that day was reported to be 102 F. July 20 the eyelids began to swell and a morbilliform rash appeared on the trunk. The rash soon spread over the entire body and became very

Fig. 1.—Appearance of patient three days after hospitalization showing distribution of dermatitis on the face and upper extremities.

pruritic, whereas the edema extended to the trunk and extremities. July 25 he noted transient numbness and weakness in the legs. The next day he began to vomit frequently. July 27 he was admitted to the Receiving Hospital and at this time came under our care.

The past history was irrelevant. He had been a labeler in a bottling works. On admission the patient was well developed and well nourished and weighed 175 pounds (79 Kg.). The temperature was 101 F., the pulse 120, the respiration rate 22. There was a bright red confluent maculopapular eruption over the entire body. In addition there were many purpuric spots on the hands, feet and legs. No urticarial lesions were present. There was generalized edema most marked on the face and upper extremities. The lips were distinctly cyanotic. There was no evidence of hemorrhage from the mucous membranes. The heart and lungs were normal. The blood pressure was

and vomiting ceased in three days. The edema was slowly absorbed. The purpuric spots ceased to appear after the first week in the hospital. The skin eruption and pruritus, however, were refractory to aqueous and oily lotions and colloid bath. Desquamation began on the hands and gradually extended over the entire body. At that stage the rash resembled the exfoliative dermatitis due to arsenamine.

A patch test August 22 was definitely positive. In addition to an acute dermatitis beneath the patch there was a flare up in the skin eruption elsewhere with an increase in pruritus a

recurrence of the purpura, and a rise in the eosinophil count from 1,640 per cubic millimeter to 3,760 per cubic millimeter.

The patient was discharged to the outpatient department August 30. A dull red, confluent, papulosquamous eruption was still present on the hands, feet and legs. Prostatic mass produced a thin purulent discharge which revealed gram positive staphylococci but no gonococci.

COMMENT

The fact that sulfanilamide was the only drug taken before the eruption appeared, together with the positive patch test, would indicate that it was responsible for the dermatitis. Since the blood urea level and the urea clearance test were normal in this case, the poisoning cannot be attributed to renal insufficiency. It is noteworthy that 50 grains (3.3 Gm) was taken daily for twenty-five days before any toxic symptoms developed. Such symptoms as weakness, lassitude, dizziness and anorexia which have been considered of minor importance preceded the serious toxic manifestations by three days during which only an additional 25 grains (1.6 Gm) of the drug was taken. The wisdom of administering sulfanilamide in such doses over so long a period without sulfanilamide determinations of the blood may be seriously questioned.

Certain other features of this case deserve brief comment. The leukocytosis and eosinophilia were much greater than in

Fig. 2—Distribution of purpura on foot three days after hospitalization.

the cases of arsenical exfoliative dermatitis studied by Towle and Swartz,⁶ in which the total leukocyte count averaged 12,400 and the eosinophils 10 per cent. The blood picture was not that of a leukemia. The purpura was probably due chiefly to increased capillary permeability. The jaundice was of short duration and was associated with slight transient impairment of hepatic function. Although there was distinct evidence of no evidence of sulfhemoglobin or methemoglobin was found on spectroscopic examination. The carbon dioxide combining power of the blood fell from 55 volumes per cent on July 2 to 28 volumes per cent on August 9. During this period the patient received 45 grains (3 Gm) of calcium carbonate and 45 grains of calcium lactate daily in addition to a high carbohydrate diet and intravenous administration of dextrose. The acidosis quickly cleared up after the administration of sodium bicarbonate which had previously been avoided because of edema.

SUMMARY

A severe exfoliative dermatitis accompanied by edema, purpura, marked leukocytosis and eosinophilia, acidosis and transient jaundice developed in a patient who had taken 1325 grains (88.3 Gm) of sulfanilamide over a period of twenty-eight days for the treatment of gonorrheal infection.

DEATHS DUE TO ELIXIR OF SULFANILAMIDE-MASSENGILL

REPORT OF SECRETARY OF AGRICULTURE
SUBMITTED IN RESPONSE TO
HOUSE RESOLUTION 352 OF NOV 18, 1937,
AND
SENATE RESOLUTION 194 OF NOV 16, 1937

During September and October of 1937 at least seventy-three persons died as a direct result of taking the drug known as "Elixir Sulfanilamide." Twenty other persons who took the "elixir" died but it has not yet been established that this drug was exclusively responsible. The ninety-three deaths occurred in fifteen states, as far east as Virginia, as far west as California.

"Elixir Sulfanilamide" was manufactured and sold by the S E Massengill Company of Bristol, Tenn. According to the firm's books 240 gallons was manufactured. The entire amount has been accounted for.

Before the "elixir" was put on the market, it was tested for flavor but not for its effect on human life. The existing Food and Drugs Act does not require that new drugs be tested before they are placed on sale.

Since the Federal Food and Drugs Act contains no provisions against dangerous drugs, seizures had to be based on a charge that the word "elixir" implies an alcoholic solution, whereas this product was a diethylene glycol solution. Had the product been called a "solution" rather than an "elixir," no charge of violating the law could have been brought.

Of the 240 gallons manufactured, 228 gallons and 2 pints has been seized under federal and state laws, destroyed, collected as laboratory samples or wasted by spillage and breakage. Eleven gallons and 6 pints was dispensed on prescriptions or over the counter sales. Of this amount about half was consumed and caused the deaths, the other half was retrieved before consumption.

The lethal effect of the "elixir" was due to its content of diethylene glycol.

Sulfanilamide is the name of one of a group of closely related chemicals first reported in European medical literature of 1935 to have been used for drug purposes. An editorial from THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, attached as exhibit A,¹ shows that sulfanilamide is potentially dangerous but that properly used it may be brilliantly successful in treating various infections.

The fatal "elixir" was rushed onto the market without adequate test to determine whether or not diethylene glycol may be safely used as a solvent for sulfanilamide despite previously published reports in scientific literature showing that diethylene glycol might be dangerous when taken internally. A few simple and inexpensive tests on experimental animals would have quickly demonstrated the toxic properties of both diethylene glycol and the "elixir."

This report was released to the press on November 26 and is reproduced with minor deletion.—Ed

¹ Sulfanilamide—A Warning editorial J A M A 109 1128 (Oct 1937)—Ed

It will be observed that the preparation is a semi-secret one, that the presence of diethylene glycol is not disclosed, and that no warning of danger appears.

Most of the drug was administered on physicians' prescriptions.

HOW THE "ELIXIR" WAS PRODUCED

Dr Samuel Evans Massengill is sole owner of the S E Massengill Company, of Bristol, Tenn. He holds the degree of Doctor of Medicine and was licensed to practice medicine in 1900. His letterhead bears the statement "Purveyor to the Professions of Medicine and Pharmacy since 1897."

Mr Harold Cole Watkins, chief chemist and pharmacist of the company, holds a degree of Pharmaceutical Chemist. Since 1900 he has been engaged as pharmaceutical, analytical and research chemist by various firms. He joined the Massengill Company in 1935.

For some time before putting "Elixir Sulfanilamide" on the market the S E Massengill Company had been marketing sulfanilamide in capsule and tablet form. In June 1937 the firm's salesmen reported a demand for the drug in liquid form. Near the end of July Mr Watkins, according to his own statement, undertook the problem of finding a suitable liquid vehicle for sulfanilamide. Since sulfanilamide is insoluble in the various liquids commonly employed in making medicines, he tried a number of other solvents. Diethylene glycol was found to dissolve as much as 75 grains of sulfanilamide per fluidounce, but in that concentration it tended to separate out on chilling. Accordingly he decided on 40 grains per fluidounce as a stable preparation and devised the following working formula:

Sulfanilamide	58 3/4	pounds
Elixir flavor	1	gallon
Raspberry extract	1	pint
Saccharin soluble	1	pound
Amaranth solution 3/16	1 1/2	pints
Caramel	2	fluidounces
Diethylene glycol	60	gallons
Water q s	80	gallons

According to Mr Watkins, no tests were made to determine the toxicity of either the separate ingredients or the finished product, or to determine by well known methods available for the purpose whether or not the sulfanilamide decomposed in the diethylene glycol. The so-called control laboratory merely checked the "elixir" for appearance, flavor and fragrance. Dr Massengill confirmed Mr Watkins' statement that no experimental animals were used or clinical tests of any kind made to determine either the effectiveness or the toxicity of the drug before it was put on the market.

Distribution of both commercial [633 shipments] and sample [671-one and two ounce bottles] lots extended over the period from Sept 4, 1937, up to and including Oct 15, 1937.

THE FOOD AND DRUG ADMINISTRATION STEPS IN

The first word of deaths from an unidentified sulfanilamide preparation reached the Food and Drug Administration on Oct 14, 1937, through a telephone call from a New York physician associated with a large drug manufacturing concern. He repeated advices, presumably received through professional or trade contacts, that fatalities had occurred at Tulsa, Okla.

² This formula is in substantial agreement with that determined by analysis by Schoeffel et al of the A M A Chemical Laboratory J A M A 109 1531 (Nov 6) 1937.—Ed

³ The headquarters office of the A M A also telegraphed to the Food and Drug Administration on the same day concerning the presence in the mixture of diethylene glycol.—Ed

Immediately instructions to investigate the report were issued by telegraph to the Kansas City Station of the Food and Drug Administration which is the nearest station to Tulsa. A representative of the administration arrived in Tulsa the following day. He reported by telegraph on Saturday, October 16, that nine deaths had already occurred in Tulsa, including eight children with streptococcic sore throat and one adult with gonorrhea, and that all had taken a product labeled "Elixir Sulfanilamide, The S. E. Massengill Company, Manufacturing Pharmacists, Bristol, Tenn.-Va." [Seizure of all outstanding shipments was immediately ordered.]

Shipping records showed that the suspected "elixir" had come from a Massengill establishment in Kansas City, to which the station immediately sent inspectors. Also an inspector from the Cincinnati station, which is the nearest station to Bristol, and a medical officer from the administration's headquarters at Washington, were sent at once to Bristol.

Inspectors from the New York and San Francisco stations were assigned to investigate distributions from these points.

It was learned that the Massengill Company, following reports of the poisonous effects of the "elixir," had sent out approximately 375 telegrams from Bristol and additional telegrams from its branch houses totaling, according to the firm's statement, some 1,100 in all, requesting the return of outstanding shipments. The texts of these wires follow:

From the Bristol office to customers, on October 15:

"Do not use elixir sulfanilamide shipped. Return our expense."

To salesmen on the same date:

"Elixir sulfanilamide discontinued. Pick up as rapidly as possible all sold in your territory."

From the Kansas City branch to jobbers, druggists and doctors who had received the product, on October 15:

"Have withdrawn product elixir sulfanilamide. Please return unused stocks immediately."

From the New York branch to customers on October 16:

"Return for credit all elixir sulfanilamide you have of our manufacture. Stop. We shall appreciate prompt attention."

On or about October 15, on telegraphed instructions from the Bristol office, the San Francisco branch of the firm instructed its salesmen to have outstanding stocks returned. However investigation revealed that no attempt had been made by that branch to communicate directly with dealers and doctors.

On October 16 the Bristol office wired the New York branch:

"Discontinue sale elixir sulfanilamide. Stop. Wire all salesmen immediately pick up sold. Stop. Wire direct all customers sold to return stock unused."

On the same date the New York branch wired to thirteen of its salesmen who were thought to have sold the elixir and wrote to its remaining twenty-six salesmen, one of whom was in Puerto Rico. Telegrams and letters were practically identical.

Discontinue the sale of elixir of sulfanilamide. Pick up and return all orders of this item previously sold. We are discontinuing immediately the manufacture of this item."

Since these telegrams and letters gave no indication of the dangerous character of the product and were

not calculated to impress receivers with the emergency character of the call for returning the goods, the inspector assigned to the Bristol office insisted that the firm issue the following telegram, dated October 19, to all persons who were listed as having received shipments of the "elixir" from Bristol:

"Imperative you take up immediately all elixir sulfanilamide you dispensed. Product may be dangerous to life. Return expense."

Following similar insistence by the San Francisco, Kansas City and New York inspectors, the branch at those points sent similar telegrams to all consignees, on or about October 19.

As a result of these telegrams, large quantities of the "elixir" were returned to the manufacturers' establishments and there taken under local or federal control. But the extremely dangerous character of the drug necessitated the most searching check to guarantee as far as humanly possible, its complete apprehension. Practically the entire field force of 239 Food and Drug Administration inspectors and chemists were assigned to the work. They had the wholehearted and effective cooperation of state and local food, drug and health authorities. As an additional aid, warnings by newspaper and radio were broadcast.

In spite of the manufacturer's telegrams many shipments were found still in dealers' hands. Innumerable prescriptions filled from these lots, as well as from shipments returned to the manufacturer, were found to have been only partly consumed by the patient and so were recovered.

The essential steps in tracing and apprehending the poisonous drug were (a) listing names and addresses of consignees, dates of shipment, and amounts shipped from the four establishments of the manufacturer; (b) following these to the primary consignees and seizing, if still intact in their possession, (c) if partially used, seizing the residue and following and procuring the distributed portions if not already consumed; (d) checking on lots reported returned to the manufacturer and definitely ascertaining whether such returned lots were intact; (e) if returned lots were not intact searching for dispensed portions.

The magnitude of the task of listing distributions is indicated by the fact that thousands of order slips had to be examined, one by one, in the four distributing houses and that in some cases this procedure had to be repeated in wholesale and retail drug stores to determine what redistributions had occurred. In one establishment alone, 20,000 sales slips were examined.

The task was complicated by the fact that distribution was not made exclusively on physicians' prescriptions which normally would have recorded the name of the patient, but that over the counter sales were made to purchasers, who in some cases were entirely unknown to the druggist. In some instances, doctors had no record of the names and addresses of patients to whom they had prescribed, or the names recorded were fictitious.

The task of interviewing promptly the approximately 200 salesmen employed by the Massengill Company in order to account for salesmen's samples and to check the distribution of physicians' samples and commercial shipments, presented serious difficulties in some cases. A typical instance was that of a salesman who later story includes part of Maryland and Virginia. He first reported to be at a hotel in Washington D. C. He was not there. Forwarding address at 11

Mich., and in Baltimore were investigated only to learn that these were for another man of the same name. After four days' search, the salesman was found at University Park, Md. One salesman in Texas was thoroughly uncooperative and was put in jail by the state authorities before he decided to reveal the necessary information.

At East St. Louis, Ill., forty-nine prescriptions, all for colored people, were filled from two shipments. The only identification on some of the prescriptions were such notations as "Betty Jane, 9 months old" or "Mrs. Jackson (no address)." In a very few instances, recipients of prescriptions bearing no identification have not yet been found, although every effort has been made to warn them by newspaper and radio.

THE PROBLEM BEFORE PHYSICIANS AND PHARMACISTS

Most of the physicians and pharmacists involved in dispensing the "elixir" cooperated willingly and effectively in apprehending outstanding prescriptions.

In contrast was the attitude of a South Carolina doctor, who told the inspector he had dispensed 1 pint 15 fluidounces to three white patients and two Negroes, whose names he did not reveal. He insisted that none of these patients had died. Information acquired by the inspector from other sources showed that the doctor had administered the elixir to seven patients, that three survived, and that a white man, a white girl, and two Negro men had died. One of the fatal prescriptions was traced through neighborhood gossip describing the symptoms of the fatal illness of a Negro employee of a lumber mill. The inspector recognized the symptoms as characteristic of "elixir" poisoning and through the mill superintendent found the victim's sister. She remembered that the doctor had given her brother some red medicine about October 2 or 3. She said that, in accordance with their custom, all medicines, glasses, spoons, etc., had been placed on the grave, which was about 1½ miles back in the fields. Accompanied by the Negroes, the inspector walked to the wooded knoll with its single mound of fresh earth on which lay several bottles, dishes and spoons. One 4 ounce bottle contained about one ounce of the "elixir." It bore the weatherbeaten but legible prescription label of the doctor.

An inspector investigating a Georgia drug store listed as having received one gallon of the "elixir" was informed that the shipment had been returned to the manufacturer at Bristol after only one lot of 6 ounces had been dispensed for one patient. Subsequent investigation showed that this patient had suffered no ill effects. But the inspector assigned at Bristol for the purpose of checking returned lots found 12 instead of 6 ounces missing from the gallon bottle returned by this druggist. Further investigation showed that two additional lots had been dispensed and had caused two deaths.

EFFECTS OF THE DRUG

The victims of the "elixir" were ill from about seven to twenty-one days. They suffered intense pain. All exhibited very much the same symptoms: stoppage of urine, severe abdominal pain, nausea and vomiting, and stupor, convulsions preceded death in some cases. Many persons who took the drug discontinued its use with the onset of unfavorable symptoms and recovered. One person took as much as 7½ fluidounces without ill effect. One child died from less than 2 fluidounces

ACTION UNDER THE LAW

Twenty-five seizures of the "elixir" were effected under the federal Food and Drugs Act. Many lots were seized or embargoed by local officials through action under state or city laws.

The distribution of the shipments from the four establishments maintained by the manufacturer of the "elixir" and the deaths that occurred are shown in the map attached as exhibit B.⁴

Citations are already in preparation for issuance to the manufacturer, in accordance with established procedure, calling on him to show cause why the cases should not be referred to the federal courts for criminal prosecution.

In September 1934 and March 1937 the S. E. Massengill Company was convicted in criminal prosecutions and paid fines for violations of the Food and Drugs Act as recorded in notices of judgment attached as exhibit C. Also included in this exhibit is a notice of seizure of a shipment of one of this firm's drugs.

Records of the Post Office Department show that in 1929 H. C. Watkins the Massengill Company chemist who made the "elixir" was distributing a medicine represented to reduce weight to bring about perfect slenderness and to cause the body to acquire a trim, youthful athletic look. On Oct. 30, 1929, the Watkins Laboratories and others were cited by the Solicitor of the Post Office Department to show cause why a fraud order should not be issued. Mr. H. C. Watkins filed a stipulation with the department agreeing that the sale of the product would be abandoned and not resumed at any future time.

LIMITATIONS OF THE LAW

As indicated earlier in this report, the only basis of action under the Food and Drugs Act against the interstate distribution of the "elixir" was the allegation that the word implies an alcoholic solution whereas the product was a diethylene glycol solution. The fact that the law contains no specific definition of "elixir" may be responsible for Dr. Massengill's statement in his letter to the American Medical Association, carried in the press of November 3, "I have violated no law."

Most drug manufacturers recognize a responsibility to the public far greater than that imposed by existing law. Some are known to have considered making a solution of sulfanilamide in diethylene glycol before the "elixir" was put on the market but abandoned the idea on investigating the toxicity of the solvent. But the attitude of some drug makers is exemplified in Dr. Massengill's statement carried by the press on October 23:

"My chemists and I deeply regret the fatal results but there was no error in the manufacture of the product. We have been supplying legitimate professional demand and not once could have foreseen the unlooked-for results. I do not feel that there was any responsibility on our part. The chemical sulfanilamide had been approved for use and had been used in large quantities in other forms, and now its many bad effects are developing."

That evidence of possible danger from the internal administration of diethylene glycol was available prior to the marketing of the "elixir" is shown by the attached exhibit D.⁵

That a few simple tests on experimental animals would have demonstrated the lethal properties of the elixir is evident from the work reported by the American Medical Association in exhibit E.⁶ These results were confirmed independently by the Division of Pharmacology of the Food and Drug Administration in work yet unpublished.

4 A map showing the number and distribution of the deaths was published in THE JOURNAL November 20, p. 1724.—Ed.
5 von Oettingen, W. F. and Jirouch, E. A. The Pharmacology of Ethylene Glycol and Some of Its Derivatives in Relation to Their Chemical Constitution and Physical Chemical Properties. J. Pharmacol. & Exper. Therap. 42: 355 (Aug.) 1931.—Ed.
6 Elixir of Sulfanilamide-Massengill. Chemical, Pharmacologic, Pathologic and Necropsy Reports. Preliminary Toxicity Reports on Diethylene Glycol and Sulfanilamide. Special article from the A. M. A. Chemical Laboratory. J. A. M. A. 109: 1531 (Nov. 6) 1937.—Ed.

While the "elixir" incident has been spectacular and has received much publicity, aside from the brevity of the period in which the killings occurred it is but a repetition of what has frequently happened in the past in the marketing of such dangerous drugs as dinitrophenol, cinchophen and other toxic substances.

It is worthy of note that, shocking as these instances have been, the actual toll in deaths and permanent injury from potent drugs is probably far less than that resulting from harmless nostrums offered for serious disease conditions. In these cases the harmful effect is an indirect one. Sick people rely on false curative claims made for worthless concoctions and thus permit their disease to progress unchecked. It may be too late when they lose confidence in the nostrum and seek rational treatment.

RECOMMENDATIONS FOR LEGISLATION

To protect the public from drugs which, like the "elixir," are dangerous because of their inherent toxicity, it is the department's recommendation that legislation be enacted to provide at least the following:

1. License control of new drugs to insure that they will not be generally distributed until experimental and clinical tests have shown them to be safe for use. The definition of what constitutes a new drug should include (a) substances which have not been used sufficiently as drugs to become generally recognized as safe, (b) combinations of well known drug substances where such combinations have not become generally recognized as safe, and (c) well known drug substances and drug combinations bearing label directions for higher dosage or more frequent dosage or for longer duration of use than has become generally recognized as safe.

Exemption should be made for new drugs distributed to competent investigators for experimental work. A board of experts should be provided who will advise the Secretary of Agriculture on the safety of new drugs.

It is the department's view that no other form of control will effectively safeguard the public from the dangers of premature distribution of new drugs. To increase the penalties for violations and to require full disclosure of ingredients would be helpful but by no means fully adequate.

In the interest of safety, society has required that physicians be licensed to practice the healing art. Pharmacists are licensed to compound and dispense drugs. Electricians, plumbers and steam engineers pursue their respective trades under license. But there is no such control to prevent incompetent drug manufacturers from marketing any kind of lethal potion. It should be remembered that Dr. Massengill and his chemist Watkins are far better equipped from the standpoint of technical training than many other persons now engaged in the manufacture of drugs.

2. Prohibition of drugs which are dangerous to health when administered in accordance with the manufacturer's directions for use. This would provide a more appropriate basis of action than that on which proceedings were instituted against the "elixir." A number of dangerous drugs are now on the market against which not even a trivial charge of violation can be made.

3. Requirement that drug labels bear appropriate directions for use and warnings against probable misuse. Much injury results from insufficient directions and from lack of warning against overuse or administration to children or use in diseased condition where the drug is dangerous or possibility of drug addiction.

4. Prohibition of secret remedies by requiring that label disclose fully the composition of drugs. Many foreign countries now impose this requirement. Many drugs manufactured in the United States are exported to such countries under labels bearing such disclosure. The same drugs are sold to our citizens under labels that give no hint of their composition.

The physician, and the consumer who acts as physician to himself, both have a right to know what they administer.

Many poisoning cases result from choice of the wrong bottle from the home medicine cabinet, or from bottles left within the reach of small children. In such cases attending physicians are able to proceed intelligently and administer the proper antidotes or other treatment only at labels carry full disclosure of composition. Delays in obtaining this information by communicating with the manufacturer may often mean the difference between life and death.

Physicians are also handicapped in arriving at a correct diagnosis and beginning appropriate treatment when patients come to them after unsuccessful attempts

at self medication with secret remedies. The effect of such remedies may give rise to symptoms leading to erroneous diagnosis. But even if the diagnosis is correct, the kind of treatment to be used may depend on what the patient has been taking. Again in such circumstances, label declaration of composition may mean the difference between life and death.

The foregoing recommendations are limited to provisions which the department believes should be enacted to safeguard the public from the dangers of drugs of one type. That type includes the inherently toxic drugs such as the "elixir," dinitrophenol and cinchophen. Many additional points should be considered if adequate protection is to be extended against even more widespread dangers to health and other abuses of public welfare arising from the inadequate control authorized by the present law over various other types of drugs.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

GENERAL ELECTRIC MODEL F QUARTZ MERCURY ULTRAVIOLET LAMP ACCEPTABLE

Manufacturer: General Electric X-Ray Corporation, 2017 Jackson Boulevard, Chicago

This Model F Quartz-Mercury Ultraviolet Lamp is designed for use in the office or hospital under the direction of a physician. It is arranged to operate solely on alternating current but special equipment may be procured where only direct current is available. The source is a quartz-mercury Uviarc burner, similar to the previously accepted source (THE JOURNAL, Dec 16, 1933 p 1967) but designed so as to minimize obstruction to direct or reflected radiation. It builds up in four minutes and cools in approximately six minutes. The unit is self starting without tilting.

The reflector is chromium plated with a mat finish. The burner housing is equipped with easily manipulated shutters which provide a means of closing off the radiation without turning off the burner. A self winding type meter for reading the distance directly from the burner to the skin of the patient is built into the burner housing. The burner housing can be adjusted to treat a patient prone sitting or even standing. The transformer is mounted in an ornamental base. The weights the lamp, thus preventing it from tipping easily. The 50 or 60 cycle lamps weigh 85 pounds, the 25 cycle or 100 cycle lamps approximately 100 pounds. The on and off switch and control provided, is operated by a foot switch projecting from the base.

The quartz mercury vapor burner consists of a single quartz tube approximately three fourths inch in diameter and 6 1/2 inches long to each end of which is sealed an electrode similar in appearance to the anode of a standard Lyrc. Its length is about 10 1/4 inches. The burner operates directly on alternating current through a special transformer located at the base of the lamp. No tubular tungsten rheostat or other devices or adjustments are required. The transformer is provided with taps to compensate for various line voltages which are adjusted at the time of installation and are touched artery and make the line voltage standard.

General Electric Model F Quartz Mercury Ultraviolet Lamp

siderably. As the line demand is low approximately 400 watts, the lamp may be operated from practically any convenient outlet of suitable voltage and frequency.

At the 30 inch treatment distance the extreme limits of the radiation field measure approximately 46 by 54 inches. At a 40 inch treatment distance it measures approximately 61 by 108 inches. The intensity and quality of the radiation are similar to those produced by the Council-accepted models A, B and C. The time required for an erythema dose is about one minute at a distance of 30 inches.

The burner housing is mounted on a bracket atop the upper part of a two section telescopic tube column counterbalanced by means of a spring within the column. The housing, if permitted, will assume a position approximately half way between the lowest and highest position. The range of adjustment is between 7 feet and 4 feet, 10 inches from the floor.

Lamps are available for operation at 115 or 230 volts, 25, 50 or 60 cycles. The actual frequency available must be within two cycles of the rated frequency.

The lamp was placed in a clinic acceptable to the Council for investigation. Tests were made to substantiate the erythemic claims made for it by the manufacturer. It was found to produce a minimal erythema in one-half minute or less at 30 inches distance, in the average person. It appears to be a satisfactory device for the administration of ultraviolet radiation.

In view of the foregoing report the Council on Physical Therapy voted to include the General Electric Model F Quartz-Mercury ultraviolet lamp in its list of accepted devices.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

THE STATUS OF MANDELIC ACID

A report on mandelic acid by Dr. William F. Braasch, Rochester, Minn., was endorsed by the Council and published as a preliminary report (THE JOURNAL March 27, 1937, p. 1033). The conclusion to this report was as follows:

It would appear that the oral administration of mandelic acid is followed by elimination of bacillary infection in the urinary tract in a large percentage of uncomplicated cases. There is no clinical evidence to indicate that it is a severe renal irritant in the presence of a normal renal function provided it is not continued longer than two weeks. Its use is contraindicated when there is evidence of renal insufficiency because of the possibility of causing renal irritation and since (in this condition) it is usually not excreted in sufficient concentration to be bactericidal.

Dr. Braasch's report stressed the undesirable effects of mandelic acid therapy. These included occasional nausea, diarrhea, renal irritation and hematuria. Since the appearance of the preliminary report, other cases presenting these symptoms have been recorded although evidence of serious or permanent renal damage has not been presented.

The toxic symptoms do not seem to be of sufficient intensity or duration to contraindicate the cautious use of the drug. The possibility of their occurrence must, however, be emphasized and is sufficient reason for insisting that the drug be used only under the careful supervision of the physician.

Owing to the somewhat enthusiastic reports which have appeared in the literature, mandelic acid is already extensively employed. In Braasch's report it was shown that the drug is bactericidal in a large percentage of cases of uncomplicated urinary infection being especially effective in bacillary infections. It is helpful as a preliminary to instrumentation or surgical treatment of the urinary tract. In some cases in which the bacteria are not completely eliminated from the urine, there has been repeated reduction in the degree of infection and improvement in subjective symptoms. Further experience has not invalidated the general truth of these claims.

The Council voted therefore, to accept mandelic acid for inclusion in New and Nonofficial Remedies.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

MANDELIC ACID—Phenyl-glycolic acid, alpha-hydroxy alpha-toluic acid, the synthetically prepared racemic (*d,l*) compound of the formula $C_6H_5CH(OH)COOH$.

Actions and Uses—Mandelic acid is a nonmetabolizable substance which when administered by mouth is excreted unchanged in the urine, and if the pH of the urine is kept at 5.5 or less it is rendered bactericidal or bacteriostatic against *Escherichia coli*, *Aerobacter aerogenes*, *Streptococcus faecalis* and organisms of the *Proteus*, *Pseudomonas*, *Alcaligenes*, *Salmonella* and *Shigella* groups. The acidity should be controlled by frequent determinations of the pH . In cases in which the acidity is not reduced to pH 5.5 or less, other acidifying agents such as ammonium chloride, ammonium nitrate or nitrohydrochloric acid may be administered concurrently providing there are no contraindications. The ketogenic diet may also be employed. Fluid intake should be restricted to an amount not exceeding 1,200 cc daily. It is usually neither necessary nor advisable to continue mandelic acid therapy longer than from twelve to fourteen days, as renal irritation may ensue. Nausea, diarrhea, dysuria and hematuria may also occur occasionally, requiring reduction in dosage or interruption of therapy. Mandelic acid should not be administered in the presence of renal insufficiency, as an inadequate concentration is obtained in the urine, renal irritation may result, and serious acidosis may occur from retention of the acid.

Dosage—The usual dosage is 3 Gm four times a day either as the free acid or in the form of the sodium or ammonium salt. An additional acidifying agent is usually required when the sodium salt is employed.

Mandelic acid is prepared by allowing sodium cyanide to react with the sodium bisulfite addition compound of benzaldehyde. The mandelonitrile thus formed is isolated and hydrolyzed to give the impure acid which is separated and purified.

Mandelic acid is a white crystalline compound which gives a colorless clear solution in water, alcohol and alkali. It is odorless and possesses a sharp, salty taste. The solubility is 16 Gm in 100 cc water at 20°C, 53.6 Gm in 100 cc ethyl alcohol at 16.5°C. The melting point of the substance is 118-120°C (microscopic heating stage).

Mandelic acid is slightly unstable, slowly turning yellow when exposed to light, reacts with alkalis and basic substances. A saturated aqueous solution reacts strongly acid to Congo red test paper and slightly acid to cresol red paper.

Dissolve about 0.25 Gm of mandelic acid in 10 cc of water and add two drops of ferric chloride test solution; a bright yellow color is produced.

Dissolve about 0.25 Gm of mandelic acid in 5 cc of water in a test tube; to this solution add 5 cc of concentrated sulfuric acid, agitate the test tube and contents for a few seconds, then add 10 cc of concentrated sulfuric acid and mix contents by a twirling motion; a purple color slowly forms if the test tube is allowed to stand for a few minutes and a strong odor of benzaldehyde is noticed.

The moisture content of mandelic acid should not exceed 0.5 per cent. *d,l* mandelic acid complies with the U.S.P. tests for heavy metals. The U.S.P. XI (Page 471) chloride test for 1 Gm should not exceed the turbidity produced by 0.05 cc of 0.02 normal hydrochloric acid in 50 cc of solution.

The ash from 0.1 Gm *d,l* mandelic acid is negligible. Transfer about 0.1 Gm *d,l* mandelic acid accurately weighed to a beaker, add 25 cc of CO₂ free distilled water and titrate with 0.1 normal sodium hydroxide using phenolphthalein as an indicator; the alkali used is equivalent to not less than 99.3 per cent nor more than 100 per cent mandelic acid (each cubic centimeter of 0.1 normal sodium hydroxide is equivalent to 0.0152 Gm mandelic acid).

Mandelic Acid-Mallinckrodt—A brand of mandelic acid
N N R

Manufactured by Mallinckrodt Chemical Works, St. Louis. No U.S. patent or trademark.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1937, p. 133)

Ampoules Bismuth Subsalsicylate 2 grains (0.13 Gm) in Oil 1 cc—A suspension of bismuth subsalsicylate U.S.P. 0.13 Gm Chlorbutanol (chloroform derivative) 0.03 Gm and distilled water 0.10 cc in sufficient olive oil to make 1 cc.

Prepared by Sharp & Dohme, Philadelphia and Baltimore. No U.S. patent or trademark.

Bismuth Subsalsicylate in Oil 2 ounce bottle—Each cubic centimeter contains a suspension of bismuth subsalsicylate U.S.P. 0.13 Gm Chlorbutanol (chloroform derivative) 0.03 Gm and distilled water 0.10 cc in sufficient olive oil to make 1 cc.

Prepared by Sharp & Dohme, Philadelphia and Baltimore. No U.S. patent or trademark.

SULFANILAMIDE-SQUIBB (See THE JOURNAL July 31, 1937, p. 358; Oct. 30, 1937, p. 1456; and Supplement to New and Nonofficial Remedies, 1937, p. 19)

The following dosage form has been accepted:

Sulfanilamide Tablets 7½ grains

SATURDAY, DECEMBER 11, 1937

THE COUNCIL ON INDUSTRIAL HEALTH

For more than two years the Board of Trustees of the American Medical Association had under consideration the advisability of establishing a council the function of which would be to deal with matters pertaining to occupational diseases and other phases of the subject of industrial health.

A committee of the Section on Dermatology and Syphilology has for several years interested itself in the problems growing out of the widespread incidence of industrial dermatoses, and at the Kansas City session in 1936 a resolution was submitted to the House of Delegates by Dr. A. R. McComas of Missouri, requesting the Board of Trustees to continue and enlarge its study of industrial hygiene and occupational diseases and to provide for active participation in well directed efforts designed to effect better control of occupational disease.

In March 1937 a conference was held in Chicago, which was participated in by the members of the Executive Committee of the Board of Trustees and by a group of distinguished physicians who have given special study to the general subject of industrial hygiene. At the Atlantic City session the Board of Trustees submitted to the House of Delegates the recommendation of this conference, to the effect that a council, to be known as the Council on Industrial Health, be established and maintained by the American Medical Association. This recommendation received the approval of the House of Delegates, and the Board of Trustees has taken steps to establish the Council on Industrial Health and has appointed the following members, all of whom have agreed to serve: Drs. Stanley J. Seeger, Milwaukee, chairman, Harvey Bartle, Philadelphia, Warren F. Draper, Washington, D. C., Leroy U. Gardner, Saranac Lake, N. Y., Morton R. Gibbons, San Francisco, H. H. Kessler, Newark, N. J., A. D. Lazenby, Baltimore, Earl D. Osborne, Buffalo, and C. W. Roberts, Atlanta, Ga.

The organization of the Council on Industrial Health will be perfected at a meeting to be held December 10,

at which will be decided the plans for outlining the nature and the scope of the Council's activities. The creation of the Council on Industrial Health is another indication of the desire of the American Medical Association to do all that it can to promote the art and science of medicine and the betterment of the public health. It is, of course, confidently expected that the medical profession throughout the United States will support the work of the Council to the fullest possible extent.

STRAINS OF MENINGOCOCCI IN THE UNITED STATES

The meningococcus was recognized in 1887 as the cause of epidemic meningitis by Weichselbaum, who first identified this organism as a separate species. As late as 1909 it was still believed that there was no essential difference between individual members of the meningococcus group of organisms. In that year Dopter¹ discovered that some of the meningococci isolated from human beings could be distinguished from the ordinary type of organisms by agglutination reactions. Soon there were found to be a number of different subtypes of meningococci. In 1915 Gordon and Murray examined many strains of meningococci from cases occurring among British soldiers and found that all of them could be classified in four definite types: type I, type II, type III, type IV. For many years the National Institute of Health in Washington has received from persons throughout the United States numerous strains of meningococci. The strains thus received from January 1931 to March 1, 1937, have been typed according to the Gordon and Murray classification and analyzed by Branham and Carlin.² The typing was done by simple agglutination tests; absorption tests were not done, as they were not considered practical for routine purposes.

Meningococcic meningitis in the United States has returned in epidemic proportions about every ten years ever since the first outbreak in Massachusetts in 1899. The year 1931, which was the first year in the period studied by Branham and Carlin, may be considered the end of an epidemic period, and the year 1935 represents a return of epidemic conditions. About 100 strains were typed. During the epidemic years from 1932 to 1934, inclusive, the percentage of type II strains studied at the National Institute of Health rose from 4 in 1931 to 32 in 1932, remained high during the following year, and fell to 13.2 when epidemic conditions returned in 1935. The type II meningococci during the last two epidemic waves in the United States has played an insignificant part during the epidemics of the World War (1918-1919) have

¹ Zinzer, Hans, and Bayne Jones, Stanhope. A Textbook of Bacteriology, 7th ed. New York: D. Appleton Century Company, 1935, page 452.

² Branham, Sara E., and Carlin, Salie A. A Study of Meningococci Recovered in the United States Since 1930. J. Infect. Dis. 1937, 57.

the type II meningococcus was abundant. Type IV during recent years seems to have dropped out of the picture altogether. The percentage of the I-III group of meningococci has greatly increased, and these strains accounted for the epidemics that occurred during the period under investigation. In the first year of the latest epidemic wave (1935) there were received at the institute about an equal number of type I and type III strains and strains that were designated as I-III because they were agglutinated equally well by the two type serums. In 1936 there was a trend in the serologic pattern toward type I and that trend was even more marked among the cultures received during the first two months of 1937.

Of the strains of meningococci typed from active cases in man during this period, 86 per cent fell into the I-III group. Of the total number of strains reported on, only twenty were known to have been isolated from the blood of patients, and sixteen, or 80 per cent of these, fell in the I-III group. Among 451 strains studied forty-two were from meningococcus carriers, and forty-one of these carrier strains were received during the spring of 1936. Among these forty-two carrier strains the type II organism prevailed. The type II meningococcus seems to have been relatively unimportant as a cause of epidemics in the United States during the last ten years.

Thus the meningococcus group of organisms is a heterogeneous group and the prevailing type occurring in epidemics in the United States changes from time to time. These facts may account in part for the difficulty of selecting the strains to be used in the preparation of therapeutic antimeningococcus serum.

HEREDITY AND THE NEUROPATHIC CONSTITUTION

Although there have been numerous inquiries into the incidence of psychoses and other "neuropathic" conditions among the relatives of the mentally defective, statistically valid figures as to frequency have not yet been obtained. According to a recent report,¹ 80 per cent of mental defectives have a positive family history of mental deficiency. This fact, if fact it is, lends support, it is asserted, to the theory that most mental deficiency is due to hereditary factors. In order to be significant, however, it must be controlled by knowledge also of the corresponding familial history of mental deficiency for the normal population. In an attempt to ascertain the frequency of such abnormalities among the relatives of normal persons, the Mental Deficiency Committee of the Royal Medico-Psychological Association devised a questionnaire, which was circulated among the mental hospitals, with the request that it be

filled out by as many of the staff as possible. The form was arranged to insure anonymity. Four hundred and fifteen of 1,500 forms distributed were completed and returned. Of this number of persons who replied, 235 stated that they had one or more relatives with one or more of eleven "neuropathic" abnormalities. This figure corresponds to a frequency of 57 per cent. Although surprisingly high, there are several factors, the report states, disposing to give a falsely low figure: (1) the tendency of nurses with a bad family history to refuse to fill in the forms, (2) the fact that information was not asked about all possible relatives, (3) the fact that the inquiry did not include all conditions which might be considered to be of neuropathic importance.

A second question on which the forms gave some information was whether the so-called degenerative stocks are breeding faster than the more normal. Because of the difficulty in definition of "degenerative," this question may be approached statistically from a number of points of view. Five methods of approach were described in this report, none of which showed any significant difference between the abnormal and the normals. The committee was of the opinion, therefore, that there is no gross difference between the sizes of families in the normal and the abnormal groups.

This report raises several points of considerable interest, some of which have been recently pointed out by Myerson.² As a background for the study of the incidence of mental diseases, large segments of the normal population should be studied for a long time. Such a study cannot be done hurriedly. It involves more than the reading of records and the interviewing of relatives. It may require intensive studies by groups of people working together at least twenty years. Obviously these criteria have not been satisfied by the Mental Deficiency Committee report. In addition, there must be grave question as to the statistical significance of the material contained in the report when based on such a relatively small section of the population, a section moreover the completely representative neuropsychic qualities of which may be open to question. Furthermore, if only 415 out of 1,500 forms were returned, there arises the inevitable problem of not knowing what the other 1,085 forms would have shown had they been returned, and how these would have affected the percentages. This difficulty with the questionnaire and sampling method has been pointed out by numerous statisticians and has been referred to editorially on previous occasions. Thus, although no genuine attempt to extend knowledge should be condemned, it is obvious that the report in question adds but little to the factual information on the relative incidence of neuropathic conditions in the relatives of the normal.

Current Comment

DEATHS FOLLOWING ELIXIR OF SULFANILAMIDE-MASSENGILL—V

In recent issues, THE JOURNAL has presented the tragic story of ELIXIR of Sulfanilamide-Massengill, particularly in reference to its scientific aspects.¹ Elsewhere in this issue² is the report of the field work and of the investigation of the S. E. Massengill Company by the United States government. The report points out that the number of deaths which have been confirmed is seventy-three (the number confirmed by the American Medical Association headquarters, as brought out in its last report) and that in addition twenty deaths followed administration of the elixir in which the exclusive responsibility of the drug has not yet been determined. The report brings out that the only test made of the elixir was that for flavor. The manufacturing formula given coincides very closely with the observations of the A. M. A. Chemical Laboratory. Of the 240 gallons manufactured, 228 gallons and 2 pints was seized by the federal Food and Drug inspectors. Eleven gallons and 6 pints was dispensed on prescription or over the counter sales. Of the latter quantity, about one half was consumed and caused the deaths, the other half was retrieved before consumption. In this interesting summary it is shown that the S. E. Massengill Company of Bristol, Tenn.-Va., sent out telegrams October 15 to withdraw the product from the market but that they were lamentably obscure as to the reason for withdrawal. The government insisted that a stronger telegram be sent, which was done October 19. The government, it is reported, is preparing citations asking that the S. E. Massengill Company show cause why it should not be subjected to criminal prosecution in the federal courts. In this connection the Secretary of Agriculture points out that in September 1934 and in March 1937 the S. E. Massengill Company was convicted and paid fines for violations of the Food and Drug Act (Notice of Judgment 23228 and Notice of Judgment 27136). Furthermore, the records of the Post Office Department show that in 1929 H. C. Watkins, the Massengill Company chemist who devised the elixir, was in the weight-reducing business in association with the Watkins Laboratories and others who were cited by the solicitor of the Post Office Department to show why a fraud order should not be issued. Mr. H. C. Watkins filed a stipulation with the department agreeing that the sale of the product would be abandoned and not resumed at any future time. The Secretary of Agriculture emphasizes the point made by THE JOURNAL that the fatal elixir was rushed on the market without adequate tests despite previously published reports in the literature showing that diethylene glycol might be dangerous when taken internally. Other points emphasized both by THE JOURNAL and by the government are that the preparation was a semisecret one that the presence of

diethylene glycol was not disclosed and that no warning of danger appeared on the label. At present, the most important factor is remedial legislative action. The recommendations made to Congress were the subject of editorial comment last week. Since then a bill has been introduced in the Senate (S. 3071) by Senator Copeland, embodying essentially the recommendations of the Secretary of Agriculture. Certainly the public deserves protection from incompetent or callous manufacturers of drugs, whether the products are sold directly to the public as "patent medicines" or exploited to the medical profession.

CRYSTALLINE VITAMIN A

One by one the many diverse substances of physiologic significance, e. g., hormones and vitamins, are yielding the secret of their structural configuration to the persistent investigations of the chemist. Not only has the isolation and identification of each substance been of theoretical significance, but the disclosure of chemical constitution has been of tremendous aid in suggesting physiologic functions and relationship, origin, fate, and methods of detecting and determining these compounds. The possible investigations concerned with a hormone or a vitamin invariably increase in number and expand in scope when isolation in pure form and establishment of structure are effected. In some instances, however, final crystallization of the physiologically active agent has eluded the combined efforts of many investigators principally because of the nonavailability of adequate concentrates or the lability of the compound. However, such circumstances, when encountered, have not greatly impaired the progress of studies designed to determine the physiologic significance and function. Indeed, in some instances, when actual isolation in crystalline form has been difficult to achieve, the chemical behavior has become known so thoroughly as to permit surprisingly accurate prediction of the chemical constitution. These comments are particularly applicable to vitamin A. Actual isolation of the vitamin itself in crystalline form appeared desirable chiefly for definite confirmation of the mass of circumstantial evidence pointing to its actual chemical configuration. This isolation has now been attained as a result of a series of noteworthy investigations at Oberlin College.³ By the use of purified solvents, low temperatures and special technical precautions, it has been possible to isolate the vitamin in crystalline form from the liver oils of three different species of fish. Biologic assay indicates that the crystalline preparation has a value of approximately 3,000,000 international units per gram. The molecular weight determination and elementary analyses of the compound correspond to a formula already suggested for the vitamin. This dietary essential which has been known for a quarter of a century has finally been obtained in a quarter probably pure, form. This constitutes another noteworthy achievement in the records of the isolation and identification of biologically important compounds.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Annual Registration Due January 1—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licensee who does not renew his license as required above is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licensee who fails to renew his license for three successive years.

CALIFORNIA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license, and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

Dr Junius Harris Honored—Dr and Mrs Junius B Harris, Sacramento, were presented with a chest of silver at the third annual conference of county secretaries in San Francisco October 2, in appreciation of their efforts in conserving the interests of the medical profession. Dr Harris has served as president of the Sacramento County Medical Society and of the California Medical Association and is now Vice President of the American Medical Association. He also served as a member of the House of Delegates of the American Medical Association in 1929, 1930, 1932 and 1934. Mrs Harris has been active in the work of the Woman's Auxiliary.

Report on Medical Economic Survey—*California and Western Medicine* announces that the "Formal Report on Factual Data" of the California medical-economic survey which was approved at the 1934 annual session of the California Medical Association has been completed. The study aimed to determine among other things, the true incidence of sickness in the state. Paul A. Dodd, Ph.D., directed the study. The 224 page report may be purchased at \$2 a copy. The state association expended more than \$40,000 to defray part of the financial expense of the survey while the Works Progress Administration and the Federal Emergency Relief Administration carried the balance of more than \$55,000. The state department of health cooperated. The study covered 21,000 families including almost 65,000 people in twenty-six representative counties of the state.

Annual Surgical Clinic—Dr John F. Erdmann, formerly professor of surgery, New York Post Graduate Medical School Columbia University, New York, was the guest of the Los Angeles Surgical Society at its annual meeting, December 10-11. Among the speakers at the afternoon sessions were:

Dr Burns S. Chaffee, Long Beach: A Ruptured Appendix That Spontaneously Drained Through the Internal Abdominal Ring and Down the Canal of Nuck.

Dr Albert J. Scholl, Los Angeles: Hemorrhagic Cyst of the Kidney.

Dr Joseph Jellen, Los Angeles: Regional Ileitis.

Dr Albert G. Bower, Los Angeles: The Administration of Sulfanilamide.

Dr Vernon Thompson, Los Angeles: Treatment of Occlusive Vascular Diseases.

Dr Wayland A. Morrison, Los Angeles: Solitary Paratyphoid Lesion of the Large Bowel.

The annual dinner was held December 10, at which Dr Erdmann gave an illustrated address entitled "Curiosities in Surgical Practice."

COLORADO

Midwinter Clinics—The Colorado State Medical Society will present the following guest speakers in clinics and formal addresses in its annual midwinter postgraduate clinics, December 15-17, at the Shurlev-Savoy Hotel, Denver:

Dr Albert J. Brown, Omaha: tumor clinic. Treatment of Diseases of the Stomach.

Dr Herman I. Kretschmer, Chicago: clinic on prostatic obstruction. Tumors of the Kidney.

Dr A. Creme Mitchell, Cincinnati: clinic on nephritis. What I Don't Know About Endocrinology.

Dr Robert D. Schrock, Omaha: fracture clinic. Fractures of the Lower End of the Radius and Ulna.

Dr Don C. Sutton, Chicago: clinic on arteriosclerosis. Obscure Fevers.

Colorado physicians will also present papers and conduct clinics. A stag smoker will be held Wednesday evening and the banquet Friday evening. The woman's auxiliary to the Medical Society of the City and County of Denver is planning entertainment for the visiting ladies.

FLORIDA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1, with the secretary of the state board of health, and at that time to pay a fee of \$1. A licensee failing to register annually is liable to a fine of not more than \$50.

Society News—Dr Walter C. Jones, Jr., Miami, was elected president of the Florida East Coast Medical Association at its tenth annual convention, in Hollywood, November 12-13. Drs. Elbert McLaury, Hollywood, and John Randolph Perdue, Miami Beach, were named vice presidents, and Dr. Thomas C. Kenaston, Cocoa, secretary-treasurer. The fall meeting of the Florida Midland Medical Society was addressed in St. Petersburg, October 28, among others by Drs. Thomas C. Maguire, Plant City, on "Congenital Abnormalities of the Intestinal Tract"; Martin H. Stuart, St. Petersburg, "A Palliative Treatment of Acute Mastoiditis," and Harold C. McDowell, Venice, "Bone Graft of the Neck of the Femur."

GEORGIA

State Pediatric Meeting—The fifth annual scientific meeting of the Georgia Pediatric Society was held in Atlanta, December 9, with the following speakers:

Dr. Joseph Brennmann, Chicago: Acute Laryngotracheobronchitis. The Acute Abdomen in Childhood.

Dr. Ralph S. Muckenfuss, New York: Immunization Against Common Infections of Childhood. Virus Infections of the Central Nervous System.

Dr. Priscilla White, Boston: Endocrine Problems in Juvenile Diabetes. Recent Problems in Juvenile Diabetes.

Dr. Paul H. Holinger, Chicago: Bronchial Obstruction in Infancy. Atelectasis and Bronchiectasis.

Dr. Henry Clifford Sauls, Atlanta, president of the Fulton County Medical Society, gave the address of welcome.

ILLINOIS

Number of Insane Patients Doubles in Twenty-Five Years—The number of insane persons in state institutions in Illinois has doubled in the last twenty-five years, according to a report of the state department of public welfare. The commitments have increased 16% per cent during the last five years. At the same time the number of epileptic and feeble-minded persons cared for by the state has increased nearly five times over a twenty-five year period and commitments to penal institutions are 11,578 for 1937 as of October 1 as compared with 3,276 in 1912. The steady increase has been most noticeable during the ten year period between 1927 and October 1 of this year. In 1927 there were 20,540 insane persons committed to institutions in Illinois, and October 1 the total stood at 28,715, in 1912 the number of insane in state institutions was 14,426. In 1912 there were 1,479 feeble-minded and epileptic persons cared for by the state, while in 1927 this number had increased to 4,562 and at the time of the report this year it reached 6,995. Delinquents committed by the state show a smaller increase over the twenty-five year period. In 1912 there were 956 delinquents cared for, in 1927 there were 1,217 and this year the number had decreased to 1,004. The state department of public welfare was caring for 51,275 persons October 1. In 1912 the number was 25,385 and in 1927 15,644.

Chicago

Society News—At a meeting of the Society of Medical History of Chicago, November 30, Drs. Clarence A. Earle, Des Plaines, Ill., discussed "Pioneer Medicine" and William Allen Pusey, Giants of Medicine in Pioneer Kentucky. The Chicago Orthopaedic Society was addressed December 10, among others, by Dr. Ralph K. Ghormley, Rochester, Minn., on "Some Unusual Lesions of Vertebrae."

The Patterson Institute for Cancer Research—A fund of more than \$500,000 has been established for cancer research and investigation, the income of which will be used in Passavant Hospital. The institute will be known as the Patterson Institute for Cancer Research. Miss Edith Patterson, Sterling, Ill., is the donor in memory of her brother, Floyd Elroy Patterson, who died in 1928. Under the terms of the agreement between

Miss Patterson, Northwestern University and the hospital, the building occupied by the Passavant Hospital will be named the Floyd Elroy Patterson Building although the unit will continue to be known as the Passavant Hospital, it was announced. The institute will be organized as a department of the hospital with a yearly appropriation of \$12,000 for treatment and research.

LOUISIANA

Personal—Dr Lucien A Ledoux, New Orleans, has been appointed associate professor of gynecology at Louisiana State University Medical Center, New Orleans, it is reported.

Society News—At a meeting of the Ouachita Parish Medical Society in Monroe, November 4, the speakers were Drs Edgar Hull and Joseph O Weilbaecher Sr, both of New Orleans, their subjects were "Nutritional Factors in Cardiac Failure" and "The New Insulin Therapy in Diabetic Disease, Namely, Protamine Zinc Insulin," respectively.

Annual Renewal Due January 1—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

MAINE

Society News—The Portland Medical Club was addressed October 5 by Dr Roderick L Huntress on "Some Causes of Urgency and Frequency Without Urethral Obstruction."—At a meeting of the Kennebec County Medical Association in Gardiner, October 27, the speakers included Dr Henry H Faxon, Boston, on "Vascular Diseases"—Dr Richard B Cattell, Boston, addressed the Oxford County Medical Association in Bethel, October 26, on "Surgical Diseases of the Colon and Rectum."—At a meeting of the Washington County Medical Society in East Machias, October 8, Dr Laforest J Wright, Bangor, spoke on "The County Society: Its Function and Value to Members", Dr Magnus F Ridlon, Bangor, "Carcinoma of the Uterus," and Ralph W Wakefield, Bar Harbor, malpractice. Dr Wakefield addressed the fall meeting of the York County Medical Society in Kennebunk, October 6, a symposium on obstetrics was also presented by Drs Roland B Moore, Portland, Chester F McGill, Portsmouth, N H, and Thomas A Foster, Portland.

MICHIGAN

New Health Association Officers—Dr Carleton Dean, Charlevoix, director, district health department, Children's Fund of Michigan, was elected president of the Michigan Public Health Association at its seventeenth annual conference in Lansing November 11. He succeeds Dr Jacob D Brook, Grand Rapids, health officer of Kent County, who was named to the board of directors. Dr John L Lavan, health officer of Grand Rapids, was elected vice president and Marjorie Delavan, Lansing, director of the bureau of education state department of health, was made secretary-treasurer.

Occupational Diseases Made Reportable—A law requiring every physician, hospital superintendent or clinic registrar having knowledge of a case of occupational disease to report it within ten days to the state department of health went into effect October 29, according to the state medical journal. The law describes the characteristics of occupational diseases and empowers the state department of health to provide employers with the proper instruction and information to prevent these diseases.

Symposium on Occupational Disease—The Michigan Department of Labor and Industry sponsored a symposium on occupational disease at the Detroit-Leland Hotel Detroit, October 21-22. Speakers included

Dr Anthony J Lanza New York Social Aspect of Occupational Diseases
Dr John T Murphy Toledo Ohio Radiologic Aspects of Silicosis
Philip Drinker Ch E Boston Industrial Dust Hazards and Their Control
Dr J eff C Aul Boston Lead Poisoning
Dr William D McNally Chicago Poisons Under an Occupational Disease Act

Graduate Conferences on Tuberculosis—The Wayne County Medical Society, the Detroit Department of Health and the Detroit Tuberculosis Sanatorium cooperated in the fall graduate conferences which this year were devoted entirely to tuberculosis. The series of lectures and demonstrations held at weekly intervals, opened October 27 with Dr Kendall Limer-

son, New York, as the speaker on "Present Trend of Tuberculosis." Other speakers included

Dr Esmond R Long Philadelphia Importance of Protection of Child and the Young Person Against Tuberculosis
Dr James N Baker Montgomery Ala The Role of the Private Physician in Tuberculosis Case Finding
Dr John B Hawes II Boston, The Care of the Patient After Sanatorium
Dr Don M Griswold Albany N Y, Factors in the Control of Tuberculosis
Dr George G Ornstein New York The Pathogenesis of Pulmonary Tuberculosis from the Physician's Point of View

MINNESOTA

Fined for Selling Contraceptives—Mrs Cecilia Scott pleaded guilty in the district court of Hennepin County at Minneapolis November 22 to a charge of the unlawful sale of contraceptives. She was sentenced to serve sixty days in the Minneapolis Work House or pay a fine of \$75, she paid the fine. Mrs Scott stated that she came to Minneapolis in the spring of 1937 from Kansas City, Mo., that she represented the Smith Laboratory Corporation, and that they had an office at 408 Wesley Temple Building. According to the state board of medical examiners, Mrs Scott did not confine her contacts to the medical profession but went to private homes because of information that she obtained through the daily birth notices in the Minneapolis newspapers. When policemen called on Mrs Scott they were told among other things, that a physical examination could be arranged for them at the office of Arthur Kolling, a chiropractor in Minneapolis. Kolling has no license to practice medicine in Minnesota and already has been convicted of practicing illegally.

NEW YORK

Annual Registration Due January 1—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

Staphylococcal Food Poisoning—About forty cases of food poisoning attributed to the eating of chocolate eclairs were recently reported to the state department of health from Newburgh and Orange County. All the eclairs were from a single batch prepared at a local bakery during the night of October 22 and sold October 23. The eclairs were made by the pastry baker without any assistance, but two other persons were in the bakery during the night. One admitted having had a sty which had disappeared two days before. It was found also that a sty developed in another employee of the bakery October 24. The state laboratory reported that staphylococci were found in great numbers in the eclairs.

New York City

Third Harvey Lecture—Dr Cecil K Drinker, professor of physiology, Harvard University School of Public Health, Boston, will deliver the third Harvey Lecture of the current series at the New York Academy of Medicine, December 16. Dr Drinker will speak on "The Functional Significance of the Lymphatic System."

Society News—George R Cowgill, Ph D, New Haven Conn, and Dr Richard Bauer, Vienna Austria, addressed the Medical Society of the County of Kings, November 16 on "Vitamin Requirements and the Clinics" and "Diagnosis of Diseases of the Liver" respectively.—Dr Charles R Stockard, professor of anatomy, Cornell University Medical College, delivered the first and second Joseph Collins Lectures at the New York Academy of Medicine, December 2, on "The Mechanisms Operating the Body as an Integrated Unit" and "Endocrine Changes and Modifications in Emotion and Behavior." A symposium on tumors of childhood was presented at a meeting of the section of pediatric pathology December 9, by Drs Bradley L Coley, George T Pack, Hayes E Martin, William L Watson and Lloyd I Craver.

Dr Levene to Receive Nichols Medal—Dr Phyllis Aaron Theodore Levene, member of the Rockefeller Institute for Medical Research since 1907, will receive the William H Nichols Medal of the New York Section of the American Chemical Society at a meeting March 12, 1939. It was recently announced Dr Levene is honored for his study of the configurational relationships of the simpler optically active com-

compounds" He is the author of papers on proteins, nucleins, carbohydrates, lipids and problems of stereochemistry and of two monographs entitled "Hexosamines and Mucoproteins" and "Nucleic Acids" Dr Levene was graduated in medicine in Russia in 1891 and came to America in 1893 After a period of practicing medicine, he began research in biologic chemistry and in the next few years was associate in chemistry at the New York Pathological Institute

Pharmacologist Honored—Friends, students and alumni of New York University College of Medicine presented to the college an oil portrait of Dr George B Wallace, professor of pharmacology, on his completion of thirty-six years of teaching November 15 Dr Alfred N Richards, professor of pharmacology, University of Pennsylvania School of Medicine, Philadelphia, made the presentation speech and the portrait was accepted by Dr Currier L McEwen, dean of the college Dr Wallace, who is 63 years old graduated from the University of Michigan Department of Medicine and Surgery Ann Arbor, in 1897 He is a member of many scientific societies, a founder of several and has served as president of the American Society of Pharmacology and Experimental Therapeutics, the Harvey Society and the Society of Experimental Biology and Medicine He is chairman of the committee on pharmacology and drugs of the 1939 World's Fair

Hospital News—The Max and Flora Einhorn Memorial Building of the Lenox Hill Hospital was dedicated October 22 The building, erected at a cost of \$400,000, is the gift of Dr Einhorn, who has been associated with the hospital for many years It contains a twenty-five bed pavilion, an auditorium, a roof garden, a hydrotherapy department and a swimming pool—The new Central Nurses' Residence on Welfare Island, which will make possible the evacuation of unsuitable quarters at several city institutions, has recently been completed Built on a loan and grant agreement with the Public Works Administration at a cost of \$1,500,000 the new residence will provide 678 rooms The department of hospitals recently announced that a residence with 669 rooms is being completed at Kings County Hospital, Brooklyn Homes for nurses have also been built at Greenpoint, Kingston Avenue and Queens General hospitals, and extensions have been added at other hospitals There are now 2189 rooms in which nurses may live under satisfactory conditions, the announcement stated—A new building for the Bronx Eye and Ear Infirmary, recently completed at a cost of \$500,000, was opened without ceremony October 15

NORTH CAROLINA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5 if a resident of North Dakota or \$2 if a nonresident A practitioner may not lawfully practice if he has not registered If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and 50 cents for each month of default

Special Society Meetings—The North Carolina Eye, Ear, Nose and Throat Society held its annual meeting in Charlotte November 20 with the following guest speakers Drs Leroy A Schall Boston on Laryngectomy—Its Place in the Treatment of Cancer of the Larynx Wilfred E Fry Philadelphia Ocular Pathology Associated with Increased Intracranial Tension and Gabriel Tucker, Philadelphia, Gastroscopy for Diagnosis and Foreign Body Removal—At a quarterly meeting of the North Carolina Neuropsychiatric Society in Asheville October 29, Dr David C Wilson Charlottesville, Va discussed a case of neuroblastoma with Hutchinson's syndrome and Dr S Spafford Ackerly Louisville Ky a case of absence of corpus callosum confused with psychopathic personality Dr James K Hall, Richmond delivered an address in the evening on Psychiatry in Retrospect and Prospect—The North Carolina Radiological Society met in Raleigh November 11 with Dr Frank E Adair, New York as guest speaker at an evening banquet with the Wake County Medical Society on Radiation and Surgical Treatment of Breast Cancer

OKLAHOMA

Personal—Dr James A Land Hobart has been appointed medical superintendent of the Western Oklahoma Tuberculosis Sanatorium, Clinton, to succeed Dr Will C Wait who will enter practice in McAlester—Dr Shade D Neely Muskogee, has been appointed health superintendent of Muskogee County to succeed Dr Charles E White, Muskogee, and Dr Gappa M Rushing, Durant, in Bryan County to succeed Dr Henry B Huston Choctaw—Dr George W Baker, Walters, has

been appointed health superintendent of Cotton County and Dr Jessie M Harris, Wilburton of Latimer County

Society News—At a meeting of the Okmulgee-Okfuskee County Medical Society, Henryetta, October 25 the speakers all of Tulsa, were Drs Morris B Lhevine, "Diagnosis and Treatment of Carcinoma of the Breast", Andre B Carney, "Surgical Procedures Following Irradiation in Carcinoma of the Breast" and Russell C Pigford, "Legislative Measures Affecting the Medical Profession in Oklahoma"—Dr Martin R Beyer, Oklahoma City, addressed the Tulsa County Medical Society, Tulsa, November 8, on undulant fever

PENNSYLVANIA

Personal—Dr Robert C Hughes, Paoli, was elected coroner of Chester County at the recent election—Dr Dale E Cary, Lancaster, was elected mayor of the town—Dr Horace V Pike retired November 15 as clinical director of the Danville State Hospital after eighteen years as a member of the staff

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction, and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100

Philadelphia

Society News—Dr Seth A Brumm, among others, addressed the Pennsylvania State Physical Therapy Association, November 18, on "Electrocoagulation of Tonsils"—Dr Wilhelm C Hueper, Wilmington, Del, addressed the Philadelphia Urological Society, November 22, on "Experimental Production of Bladder Tumors in Animals"—Dr Edward D Churchill, Boston, delivered the Mutter Lecture of the College of Physicians of Philadelphia, December 1, on "The Pathology and Surgery of Bronchiectasis"—Dr Nathaniel S Yawger, among others, addressed the Philadelphia Neurological Society, November 19, on "Marihuana Our New Addiction"

Symposium on Biophysics—The American Institute of Physics in cooperation with the Eldridge Reeves Johnson Foundation for Medical Physics at the University of Pennsylvania sponsored a symposium on biophysics November 4-6 Among those who appeared on the program were

Detlev W Bronk Ph D director of the Johnson Foundation The Relation of Physics to the Biological Sciences
Edmund Newton Harvey Ph D Princeton N J The Physical Properties of Protoplasm
Dr Herbert S Gasser New York Electrical Signs of Biological Activities
Wendell M Stanley Ph D Princeton N J The Biophysics and Biochemistry of Viruses
Wallace O Fenn Ph D Rochester N Y The Mechanics of Muscular Contraction

Irving Langmuir, Ph D, director of research, General Electric Company, Schenectady, delivered the Johnson Foundation Lectures November 4 and 5, on "Monolayers and Multilayers and Their Applications to Biological Problems"

Pittsburgh

"Scientific Day" at Montefiore Hospital—Dr Irving Sherwood Wright New York, was the guest speaker at the annual Scientific Day of Montefiore Hospital, November 20, addressing an evening meeting on "A Critical Analysis of Recent Advances in the Study of Vascular Disease" In the morning the department of ophthalmology gave a demonstration of eyegrounds in arteriosclerosis and hypertension followed by discussions as follows Drs Verner B Callomon, on Bronchial Tumor with Atelectasis Meyer A Rosenbloom Sarcomatosis of Stomach with Metastasis to the Heart, Yale D Koskoff "Ligation of Carotid Artery for Intracranial Bruit," and Harry I Miller, Peripheral Vascular Disease"

SOUTH CAROLINA

Society News—Drs Jefferson C Pennington, Nashville, Tenn and Edgar G Ballenger, Atlanta, Ga, were the guest speakers at the annual meeting of the South Carolina Urological Association in Columbia, October 13, on Management of Calculi in the Upper Urinary Tract and Management of Tumors of the Bladder, Both Benign and Malignant respectively—Dr Irvin Abell, Louisville, Ky, President-Elect of the American Medical Association was the guest of the Columbia Medical Society, November 8, speaking on "The Relation of Diabetes to Surgery" Dr Foster M Routh discussed "The

Leukopenic Index in Food Allergy"—Dr Joseph D. Guess, Greenville, addressed the Anderson County Medical Society, October 13, on "Problems in the Management of Labor."

TENNESSEE

Personal—Dr Monroe F. Brown, Fayetteville, has succeeded Dr Frank L. Roberts as health officer of Gibson County with headquarters in Trenton. Dr Roberts is now professor of preventive medicine at the University of Tennessee College of Medicine, Memphis.

Nobel Prize Winner to Give Flexner Lectures—Dr Albert Szent-Gyorgyi, professor of medical chemistry in the Royal Hungarian Franz Joseph University, Szeged, Hungary, who received the Nobel Prize in Medicine for 1937, has been chosen to give the Flexner Lectures at Vanderbilt University School of Medicine, Nashville, for the session of 1938-1939.

Society News—At a meeting of the Dyer, Lake and Crockett Counties Medical Society in Dyersburg, November 3, the speakers were Drs Robert Lyle Motley, Memphis, on "Treatment of Cardiac Decompensation and Edema," Duane M. Carr, Memphis, "Pneumonia," and William P. Watson, Dyersburg, "Accidents During Labor."—A symposium on gallbladder disease was presented before the Memphis and Shelby County Medical Society, Memphis, October 5, by Drs Henry G. Rudner, Joseph A. Crisler Jr and Lucius C. Sanders. Drs W. Likely Simpson and William S. Anderson, Memphis, addressed the society, October 19, on "Foreign Bodies in the Air and Food Passages" and "Indications for Hysterectomy and Radium in Uterine Fibroids" respectively.

University News—Dr Harry A. Davis, instructor in pathology, George Washington University School of Medicine, Washington, D. C., is serving as acting associate professor of pathology at the University of Tennessee College of Medicine, Memphis, in the place of Dr Walter W. Brandes, who is on leave of absence because of illness. William R. Amberson, Ph.D., recently resigned as head of the department of physiology to become professor of physiology at the University of Maryland School of Medicine, Baltimore. His successor has not been appointed. Dietrich C. Smith, Ph.D., instructor in physiology, also went to Maryland as associate professor.

TEXAS

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1, with the state board of medical examiners, and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

Society News—Drs Henry G. Poncher and Arthur H. Parmelee, Chicago, were the guest speakers at a meeting of the Texas Pediatric Society in Dallas, October 23. Dr Poncher spoke on "Problems in Nutrition—Vitamins" and "Upper Respiratory Infections" and Dr Parmelee on "Congenital Syphilis" and "Conditions in the New-Born."—Drs Henry M. Winans and Robert F. Short Jr, Dallas, addressed the Grayson County Medical Society in Sherman, October 12, on "Diagnosis of Upper Quadrant Lesions" and "Surgery of Upper Quadrant Lesions," respectively. Dr Louis F. Knoepf Beaumont, addressed the Hardin-Tyler Counties Medical Society, October 12, in Kountze on "Surgical Lesions in Tuberculosis."—Dr French K. Hansel, St. Louis, addressed the Dallas Academy of Ophthalmology and Otolaryngology in October on "Etiology and Treatment of Rhinitis."—Dr Edward P. Leeper, Dallas, discussed "Heart Disease Due to Vitamin Deficiency" before the Dallas Heart Association, November 1.—Drs J. C. Alexander and Milford O. Rouse, Dallas, addressed the Ellis County Medical Society, Waxahatchie, October 13, on "Sulfanilamide as a Urinary Antiseptic" and "Diarrheas" respectively.—Drs George D. Mahon and Charles L. Martin, Dallas, addressed the Potter County Medical Society, Amarillo, October 11, on "Resection of the Right Half of the Colon" and "Treatment of Advanced Cancer" respectively.

WASHINGTON

Society News—At a meeting of the Washington State Obstetrical Association in Spokane, October 2, there were discussions of "Induction of Labor," "Analgesia and Anesthesia" and "What Is of Most Importance in Obstetrics Today." Dr Henry H. Skinner, Yakima, is president of the association and Dr Philip C. Kile, Tacoma, secretary.—Dr Henry S. Atwood, Yakima, addressed the Yakima Valley Medical Society

in Yakima, October 11, on "Spinal Anesthesia."—Drs I. G. Cheetham and Leo J. Meinberg, Portland, Ore., addressed the Cowitz County Medical Society, Longview, October 13, on "Sulfanilamide treatment of gonorrhea."—Dr Frederick Lenore, Seattle, addressed the Pierce County Medical Society, Tacoma, October 12, on "Insulin Shock in Treatment of Psycho."—At the first fall meeting of the Walla Walla Valley Medical Society, Walla Walla, October 14, Drs Frank B. Kistner and Robert L. Benson, Portland, discussed "Asthma and Hay Fever as Related to Parasinal Sinus Infection."

WEST VIRGINIA

Public Health Meeting—Dr Reece M. Pedcord Wheeling, was elected president of the West Virginia Public Health Association at its annual meeting in Charleston, November 7. Drs Charles E. Watkins, Fayetteville, and William W. Hunt, Beckley, were elected vice presidents and Dr Thomas W. Hale, Charleston, secretary. Among the guest speakers at the meeting were Drs Reginald M. Atwater, secretary of the American Public Health Association, New York, on "Today's Trends in Public Health," Halbert L. Dunn, chief statistician for vital statistics of the Bureau of the Census, Washington, D. C., "Complete Birth Registration," and Anthony J. Lanzi, New York, "The New Day in Disease Control and Prevention Through Industrial Hygiene."

WISCONSIN

Society News—Speakers before the Milwaukee Society of Clinical Surgery, November 23, were Drs Edmund W. Schacht, Racine, on "Carcinoma of the Scrotum" and Charles B. Huggins, Chicago, "What Is the Function of the Arterial Supply of the Liver?"—Dr Oscar A. Sander, Milwaukee, addressed the University of Wisconsin Medical Society, Madison, November 23, on "Silicosis."—Dr Roy P. Potter, Marshfield, addressed the Columbia-Marquette-Adams County Medical Society, Adams, November 9, on "Diseases of the Chest."

District Meeting—The annual meeting of the Fifth District of the state medical society was held in Two Rivers, October 14, with the following guest speakers: Drs Nelson M. Barker, Rochester, Minn., on hypertension; Harry L. Smith, Rochester, diagnosis and treatment of carotid sinus syncope; William S. Middleton, Madison, newer therapy of lobar pneumonia; and David A. Cleveland, Milwaukee, spinal and cerebral injuries. Dr James C. Sargent, Milwaukee, president of the state medical society, discussed society plans for the coming year.

Committee to Study Sickness Care—At the recent annual meeting of the Medical Society of Wisconsin a special committee was appointed to investigate the adequacy of sickness care in the state. Dr Raymond G. Arveson, Frederic, is chairman and the other members are Drs Henry J. Gramling and Robert W. Blumenthal, Milwaukee, Joe Newton Sisk, Madison, and Henry H. Christofferson, Colby. It is planned that the committee shall hold hearings in various parts of the state to receive complaints, opinions and recommendations of all persons in certain key centers who are familiar with the broad problem of sickness care.

PUERTO RICO

The Annual Medical Meeting—The thirty-fourth annual session of the Puerto Rico Medical Association will be held at the association headquarters in Santurce, December 17-19. Special guests will be Drs Ramon Castroviejo and Dana Winslow Atchley, New York, who will conduct clinics and give addresses on "The Present Status of Ophthalmic Surgery" and "Nephrosis and the Nephrotic Syndrome" respectively. Among others on the program will be:

Dr Manuel E. Pujadas Diaz, Santurce, Celiac Disease.
Dr Oscar G. Costa Mandry, Santurce, Study of Food Infections in Puerto Rico.
Dr Rafael Lopez Nussa, Santurce, Surgery of the Sympathetic.
Dr A. Rodriguez Ollerios, Madrid, Spain, Gastroscopy.
Dr Luis J. and Ricardo Fernandez, San Juan, Treatment of Gonococcal Ophthalmia with Sulfanilamide.
Dr Ezequiel Martinez Rivera, Rio Piedras, Venereal Disease from Public Health Point of View.
Dr Carlos Gonzalez Mayaguez, Therapeutic Use of Sulfanilamide in Infections of Streptococcal Origin.

A feature of the meeting will be three showings of the film "Diagnosis of Syphilis" prepared by the American Medical Association and the U. S. Public Health Service. The latter sessions will be held in the afternoons and evenings. The program will be devoted to clinics at various hospitals.

GENERAL

New Journal of Neurophysiology—Announcement is made of the forthcoming publication of the *Journal of Neurophysiology* under an editorial board consisting of Drs Joannes G Dusser de Barenne and John F Fulton, Sterling professors of physiology, Yale University School of Medicine, New Haven, Conn., and Ralph W Gerard, associate professor of physiology, University of Chicago. The aim of the new journal is to serve as a channel for prompt publication of original work bearing on the functions of the nervous system, peripheral and central. The publisher is Charles C Thomas, Springfield Ill.

Y M C A to Cooperate in Syphilis Campaign—The National Council of the Young Men's Christian Association has issued a bulletin urging local units to cooperate with physicians and health officials in the campaign against syphilis. The local units are urged to begin at once to (1) investigate local conditions, the prevalence of the disease and available treatment; (2) appoint committees to consider effective ways and means of aiding local medical and public health authorities; (3) hold social hygiene meetings at which syphilis is the subject for discussion; and (4) arrange with physicians for the taking of Wassermann tests in Y M C A's where practicable. It is estimated that 75 per cent of the association's members are between 11 and 30 years of age, the age group in which the public health service reports that more than half the primary syphilitic infections occur.

Conference on Maternal and Child Welfare—Miss Katharine F Lenroot, chief of the Children's Bureau, U S Department of Labor, has called a conference on "Better Care for Mothers and Babies" to be held in Washington, D C, January 17-18. A planning committee for the conference has been appointed with Mrs J K Pettengill, Detroit, president of the National Congress of Parents and Teachers, as chairman, Dr Fred L Adair, Chicago, chairman of the American Committee on Maternal Welfare, as vice chairman and Mrs Nathan Straus, New York, representing the National Council of Jewish Women, as secretary. The planning committee will represent numerous organizations in the field of health and welfare. Plans for the conference grew out of findings presented to the Children's Bureau by its advisory committee on maternal care, of which Dr Adair is chairman, the announcement stated.

Advisory Committee on Pneumonia—An advisory committee, recently appointed by Dr Thomas Parran, surgeon general, U S Public Health Service, to plan a program for pneumonia control on a national scale, held its first meeting November 12, in Washington. Members of the committee are:

Dr Donald B Armstrong, third vice president Metropolitan Life Insurance Company, New York
Dr David P Barr, Busch professor of medicine Washington University School of Medicine St Louis
Dr Russell L Cecil, professor of clinical medicine Cornell University Medical School New York
Dr Lloyd D Felton, associate in pathology and bacteriology Johns Hopkins University School of Medicine Baltimore
Dr Alfred Friedlander, dean and professor of medicine University of Cincinnati College of Medicine
Dr Roderick Heffron, Commonwealth Fund New York
Dr Ernest E Irons, clinical professor of medicine Rush Medical College Chicago
Dr Roger I Lee, consultant in internal medicine Boston
Dr George H Ramsey, assistant commissioner for preventable diseases State Department of Health Albany N Y

National Foundation for Infantile Paralysis—President Roosevelt announced November 24 appointment of thirty-four citizens of various parts of the United States to serve as trustees of the new National Foundation for Infantile Paralysis now in process of formation. According to a statement by the President when he announced the new foundation recently, its general purpose will be to lead direct and unify the fight on every phase of this sickness. "It is hoped that a fund of from \$7,000,000 to \$10,000,000 will be raised in the next five years. With this the foundation will make every effort to ensure that every responsible research agency in this country is adequately financed to carry on investigations into the cause of infantile paralysis and the methods by which it may be prevented. It also aims to develop means of enabling those already crippled by the disease to become economically independent in their own communities. The first task of the foundation will be to arrange the fifth annual 'birthday balls' to be held January 29 in honor of the President's birthday which is January 30. This year all funds from the celebration will be given to the new foundation instead of being divided as heretofore between the Georgia Warm Springs Foundation and local communities. The newly appointed trustees are: Cornelius A Bliss, John S Burke, Carle C Conway, James V Forrestal, S Parker Gilbert, W Averell Harriman, Jeremiah

Milbank, Keith Morgan, Thomas E Murray Jr, Basil O'Connor, Edward Stettinius Jr, Thomas J Watson and Clarence Woolley, all of New York, George E Allen, Commissioner of the District of Columbia, Robert V Fleming, Washington, James F Bell, Minneapolis, William L Clayton, Houston, Texas, Robert H Colley, Philadelphia, Harvey C Couch, Pine Bluff, Ark., Walter J Cummings, Marshall Field and Walter P Murphy, Chicago, Fred J Fisher, Detroit, Edsel B Ford, Dearborn, Mich., Elton Hoyt 2d, Cleveland, William F Humphrey, San Francisco, John R Macomber, Boston, Leighton McCarthy, Toronto, Robert E McMath, Bethlehem, Pa., Carroll B Merriam, Topeka, Kan., Charles E Perkins, Santa Barbara, Calif., George Rand Buffalo, Robert W Woodruff, Atlanta, Ga., and S Clay Williams, Winston-Salem N C.

FOREIGN

Typhoid in London Suburb—The *New York Times* reported November 22 that 137 cases of typhoid had occurred in the preceding fortnight in Croydon, a suburb of London, said to have modern water, drainage and health services. Seven deaths had occurred up to November 20. Tests showed that Croydon's water services had "the highest standard of bacterial purity," the *Times* reported.

CORRECTIONS

International Unit for Estrone—On page 1865 of the December 4 issue of *THE JOURNAL* in the article by R T Frank and others, the international unit for estrone (theelin, "ketohydroxyestrin") should have been given as 0.1 microgram instead of 1 microgram.

Duration of Immunity Against Diphtheria—In *THE JOURNAL*, November 20, page 1684, in the first column, second line following the word "negative" the following sentence should have appeared in the discussion by Dr M Bernard Brahdry of the paper by Dr William H Park: "For the results with precipitated toxoid I am going to present data obtained by Dr O'Brien in a group of infants who had no previous injection of antigen."

Government Services

Examination for Appointment in the Navy

Announcement is made of an examination for appointment as lieutenant (junior grade) in the medical corps of the U S Navy to be held at all naval hospitals in the United States and at the Naval Medical School, Washington, D C, beginning May 16, 1938. Candidates must be between 21 and 32 years old at the time of appointment, must be graduates of class A medical schools and must have completed an internship of one year in a hospital accredited for interns by the American Medical Association and the American College of Surgeons. Those who are interested should write to the Surgeon General, U S Navy Bureau of Medicine and Surgery, Navy Department, Washington, D C for further information concerning the examination and the procedure to follow for appearance before the examining boards.

Biochemist Wanted for Research on Syphilis

The U S Civil Service Commission announces an open competitive examination for the position of associate biochemist (syphilis research) at a salary of \$3,200 a year for a vacancy in the Syphilis Research Center, Johns Hopkins Hospital, Baltimore. The work consists of investigative or research work in antibody chemistry, pollen chemistry, the chemistry of the arsenamines or related problems. Candidates must have completed a four year college course with major study in chemistry or chemical engineering. In addition they must have had at least three years of experience or postgraduate training or a combination of these at least one year, in active investigations of the biochemistry of proteins. Applications must be filed with the U S Civil Service Commission at Washington D C before December 28. The closing date is December 31 for the states of Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 13, 1937

The Growth of Social Services

In an address to the Society of Arts, the chairman, Lord Amulree, said that year after year social legislation advanced and new means were devised for mitigating the hardships which would otherwise be felt by some members of the community. The aggregate public expenditure on education, housing, old age pensions, health insurance, unemployment insurance, unemployment assistance, public assistance or poor relief was annually about \$1,500,000,000. In addition, \$460,000,000 was collected by way of contributions from employers and employed persons. Unless some catastrophe occurred that would arrest all progress, social legislation was likely to increase. At present emphasis was being placed on physical fitness, and there was increased interest in the subject of nutrition. There was a source from which might spring numerous projects of social amelioration, such as the state subsidization of games and sports and possibly artificial cheapening of food. Concern about the birth rate might well give an impetus to the movement in favor of family allowances and the subsidizing of wages.

Some hoped that education would bring about such a standard of social behavior that all men would give their best without the stimulus of material reward or the fear of hardship. Even though that hope might be justified, it was doubtful whether such progress would keep pace with the rapid development of the social services. If not, we might be faced with serious economic and social difficulties. The problems of population might in the near future be not only quantitative. Vistas were opened which were not always pleasant. For example, there was the possibility of compulsory training, restriction of choice of employment and regimentation and control in other directions where at present we shrink from it. Would the benefit of the material advantages we desired to confer be outweighed by the price to be paid in the sacrifice of freedom?

Decrease in Blindness in Children

A bill to help the blind by reducing from 50 to 40 the age at which they become eligible for old age pensions was unanimously given a second reading in the House of Commons. The minister of health said that there were 78,000 registered blind persons in Great Britain. In consequence of increased knowledge of the causes of blindness which operated at birth or in early years and the preventive steps taken the age at which blindness occurred was becoming later. There had been a substantial fall in the numbers of blind children. Those between the ages of 5 and 16 had fallen since 1925 from 3,104 to 1,916, a decrease of more than 38 per cent. It was not practicable to train a blind person after 40 for a new occupation. This was the reason for choosing that age in the bill. The only criticism made in the debate was that still more should be done for the blind. A medical member Sir Francis Edward Fremantle complained that no similar provision had been made for the deaf whose case was almost as tragic as that of the blind. He also objected to extending a pension on a flat rate according to age and regardless of disability. The need of a blind person should be assessed and help given in a similar way to that followed in the case of ex-service men.

A Relentless War on Rheumatic Disease

In an address before the Empire Rheumatism Council Lord Horder said that the problem of rheumatism had been largely neglected from the aspect of scientific investigation and control. The reasons were not obscure. The rheumatism of the

not dramatic, they were not directly lethal, and they were specific in their causation. This very lack of a specific cause had been a potent factor in delaying thorough classification and research, a factor that was absent in such diseases as tuberculosis. It had been known for a long time that the causation of rheumatism was complex, and one after another a number of definite and important causative elements had been brought to light. We were now ready to advance systematically, both in the segregation of the different types of the disease and also in following the different indications for treatment. Since 1922, when the Ministry of Health began to reconnoiter the entrenched positions of the invading enemy, there had been increasing progress in organizing an effective attack on them. The Empire Rheumatism Council formed last year, had already organized the scientific and administrative resources of the home country and the dominions for a relentless war on rheumatic disease.

The stresses and strains of modern life had greatly increased more and more people were subjected to the bombardment of the din of the factory and of the city and to long periods of travel, often under conditions of overcrowding and jolting. The meals of thousands were hurried and defective in quantity or quality or both. A proper amount of physical exercise became more and more difficult for large masses of the people. Industry imposed on many a constant routine of small and frequently repeated movements which called for the overuse of a few muscles and the neglect of all the rest. These were the predisposing and, at times, even the determining causes of rheumatic diseases.

THE EXTENT OF THE SUFFERING

A Ministry of Health survey in 1922 showed that rheumatic disease was probably responsible for 16 per cent of the total industrial morbidity in this country and that during a year 372,600 insured persons sought medical advice for some form of rheumatic disease. The highest incidence was among metal workers, transport workers, mine workers, building workers and clerical workers, in that order. To that estimate of 372,600 insured persons had to be added those outside the insured class. They were considerable, but no basis existed for an accurate estimate. In the insured the annual monetary loss involved amounted to \$85,000,000.

Rheumatism was not often directly lethal, but in rheumatic fever and in cardiac rheumatism there was a killing process second to none in the country. A Ministry of Health report for 1924 stated that "organic disease of the heart is for the most part rheumatic in origin and organic heart disease is the cause of over one third of all deaths."

A LONG TASK

The Empire Rheumatism Council proposed a plan of coordinated research into the causative factors and treatment of all the disease in the rheumatic group. Discovery of the cause would mean not merely cure but—what is more important—prevention. But the probability must be faced that the research might prove a long one. It was planned for a seven year term. All the existing treatments would be investigated immediately, and any new ones brought to notice. Problems of infection, of biochemistry, of diet and of living and working conditions would be probed. The investigations would cover the whole area of the British Empire with its differences of climate and of habits. Also cooperation would be extended to all foreign effort. In therapeutic results could be hoped for in a short time. After arrival the standardization of the most efficient and the most practical treatment the next step would be to make it available to all classes and to see that it was applied in the early stages. In a sentence it was a ruthless war that was being planned against fellow men but against a savage enemy of the race.

Sir Kinsley Wood, minister of health, has laid the foundation stone in London of an arthritis unit, the first of its kind in this country, which has been established by the Empire Rheumatism Council. He said that one sixth of our industrial invalidity was due to rheumatism. The unit marked a new step forward. It would provide beds for research in the early stages of the disease as well as prolonged investigation by a team of workers.

Research in Immunology

In the annual report of the London School of Hygiene and Tropical Medicine it is stated that an important advance has been made by joint researches in the departments of bacteriology and biochemistry. Chemical fractions which appear to have effective immunizing powers have been isolated from the organisms of typhoid, whooping cough and cholera and from certain strains of hemolytic streptococci. A point has been reached where practical application of the results obtained with some of these organisms is within view. The work appears to be of the utmost importance and likely to give a new direction to practice in relation to the whole group of infectious diseases.

PARIS

(From Our Regular Correspondent)

Nov 6, 1937

French Gynecologic and Obstetric Congress

The tenth Gynecologic and Obstetric Congress was held October 1-2 in Paris, the president being Professor Mocquot. The three subjects chosen for discussion were medical and surgical treatment of pruritus vulvae, uteroplacental apoplexy, and treatment of incontinence and of vesicovaginal fistula.

The first paper was by Vayssiere of Marseilles on the etiology and treatment of pruritus vulvae. He said that from 8 to 10 per cent of all patients who applied for treatment at gynecologic dispensaries desired relief for this condition. Among the local causes, leukorrheal discharge was the most frequent. The pruritus was more marked during menstruation and pregnancy. Hormonal factors, such as estrogenic insufficiency, also must be searched for in the etiology. Local treatment of the cervicovaginal infection must be governed by the pH of the secretions, with acetic or lactic acid if they are too alkaline and vice versa. A 1:2,000 solution of silver nitrate is efficacious. A Trichomonas infection is best treated by acetarsone. Radiotherapy is to be recommended for cases resisting all other treatment. If there is evidence of hormone insufficiency, relatively large doses, from 3,000 to 50,000 units a week, should be given, of estradiol benzoate in oil, subcutaneously. Cotte of Lyons pointed out that surgical treatment was a last resort after all nonoperative methods had been unsuccessful. Minor methods include local injections of a 1:400 solution of quinine and urea hydrochloride, of 60 to 90 per cent alcohol and of radioactive preparations. Presacral nerve resection had given good results in ten of seventeen cases; four were partly successful and three were failures. This operation is indicated only when every other method has failed to give relief. In the discussion, Labhardt of Switzerland stated that pruritus was a symptom in inflammatory disorders of the vulva, in psychoneuroses and in vulvar leukoplakia, owing as a rule to ovarian dysfunction. The leukoplakias responded to injections of estrogen, if relatively large doses were given. Kreis of Strasbourg emphasized the necessity of a search for psychoneuroses in the etiology. Jeanneney of Bordeaux said that the choice of neutralizing solutions and antiseptics to be employed depends on the results of the chemical and bacteriologic examination of the vaginal secretions. Search should be made for diabetes, hyperglycemia, high blood urea content and syphilis next for evidences of ovarian dysfunction, and finally for disturbances of the sympathetic nervous system. Brocq and Desrous of Paris reported a case successfully treated by vulvectomy after every other method had been tried.

The second subject for discussion was uteroplacental apoplexy. Professor Couvelaire pointed out that the subject included not only retroplacental hematoma and resultant hemorrhage but also bleeding into the uterine wall, perhaps extending to all the internal genitalia and other viscera. The pathogenesis is not clear. It was thought to be related to nephritis and hypertension in multiparas beyond the age of 30, but it has been found that it is not dependent on vascular lesions or hypertension. The former play a part during pregnancy and then only the capillaries are involved. Experimentally, these accidents appear to take place in women previously sensitized to various antigens, which makes them resemble the visceral infarcts by intolerance shock as described by Gregoire and Duval. The ovum does not take any part because the same phenomena can be produced in nonpregnant animals.

The treatment was the subject of a paper by Weymeersch and Snoeck of Belgium. The incidence of uteroplacental apoplexy varies from 0.09 to 1.06 per cent according to various reports. The obstetric methods of treatment aim to empty the uterus as rapidly as possible. Surgical intervention includes conservative cesarean section (high or low) alone or followed by vaginal hysterectomy and abdominal hysterectomy. Obstetric treatment was employed in 853 of 1,080 cases, with a maternal mortality of 6.58 per cent and a fetal mortality of 61.3 per cent. Surgical treatment in 227 cases entailed a maternal mortality of 21 per cent and a fetal mortality of 70.7 per cent.

The severity and extent of the hemorrhages are not necessarily a criterion of the gravity of the case in deciding which of the three operative methods is to be selected. The time factor is the most important one. If the uterus is emptied during the first ten hours after appearance of the symptoms, the maternal mortality is 27 per cent. It rises to 40 per cent if the ten hour period has been passed. Many obstetricians, in order to judge the functional value of the uterus, inject solution of posterior pituitary intravenously following cesarean section. If the uterus contracts well, so that no late hemorrhage is to be feared, the organ is conserved. Clinically the cases can be placed in two groups so far as treatment is concerned.

1 Hemorrhage preceded, accompanied or rapidly followed by the beginning of labor. In these, expectant treatment is the best. Morphine is given to relieve the pain, the bag of waters is ruptured, solution of posterior pituitary is given and eventually low forceps are used.

2 Severe hemorrhage appearing before any signs of labor and the general condition indicating a probable uteroplacental apoplexy. Some recommend expectant treatment with artificial rupture of the bag of waters. Others, in severe cases, with marked shock and a toxic syndrome feel that only operative intervention can be considered, preferably low cesarean section.

In the discussion, Voron and Pigeaud of Lyons reported that, if the serum of patients suffering from purpura is injected into pregnant rabbits, visceral and intra-ovarian hemorrhages follow which resemble in every respect the lesions observed in uteroplacental hemorrhages in human beings. Brindeau and Lantuejol of Paris reported two maternal and thirty-one fetal deaths in forty-three cases. Normal labor occurred in twenty-five but operative intervention was necessary in eighteen. Cathala of Paris believes that obstetric procedures (especially embryotomy) are preferable to surgical treatment. Conservative cesarean section is rarely indicated. Cesarean section with hysterectomy should be reserved for cases in which embryotomy is dangerous. De Snoo and Streink of the Netherlands are partisans of obstetric methods combined with the administration of remedies to combat the shock. In 214 cases there were only eleven maternal deaths (5 per cent) but a fetal mortality of 78 per cent. Le Loner of Paris has been obliged to operate in only six of sixty-four cases, with two deaths (maternal). In two of the six a hysterectomy was necessary, with one death. Keller of Strasbourg was obliged to operate in only three of

twenty-seven cases. Eleven of eighteen women who were observed later became pregnant again and there were sixteen pregnancies with fourteen living children and no recurrence of a uteroplacental apoplexy. Ecalle and Suzor of Paris believe that a distinction should be made between premature detachment of a normally inserted placenta of toxic origin and uteroplacental apoplexy. In 14,000 obstetric cases they have observed the latter only seven times. All patients were operated on, with two deaths.

The first part of the third question for general discussion was the treatment of incontinence. The paper was read by Muret and Rapin of Switzerland. After a review of the anatomy of the female urethra, the authors stated that the most frequent cause is to be found in perineal and other lesions incident to parturition followed by incomplete postpartum involution. Next in order as causes are congenital or acquired relaxation of the tissues as well as the sequels of gynecologic procedures. As prophylactic measures, avoidance of prolonged labor, immediate repair of all lacerations and surveillance of uterine involution are to be recommended. Only surgical procedures offer any permanent relief. The various types of plastic operation were described and the conclusion was reached that an anterior colporrhaphy, which would include the sphincteric structures, would suffice in the majority of cases. A colpoperineorrhaphy should always be done at the same time.

The second part of the third question took up the treatment of vesicovaginal fistula and was presented by Andre of Nancy. As to etiology there were two groups: (a) fistulas incident to prolonged labor with pressure of the fetal head on the bladder or application of forceps and (b) operations on the uterus, especially total or radical hysterectomy and application of radium for cancer of the cervix. In the first group the fistulas are low, in the second much higher. Before any operation is planned, the relation of the fistula to the ureteral orifices must be ascertained by cystoscopic examination and the vagina should be dilated by tampons. The various types of operation were described, preference being given to the transvesical technique described by Marion, in fistulas following labor or operative procedures when the opening is very high and the vagina narrow. The transperitoneal (Legueu) method is especially to be recommended, although difficult, in high lying fistulas following total hysterectomy. In the discussion Vanverts of Lille said that immediate perineal repair required good light and technic. If these were not available it would be preferable not to attempt a primary closure but do this later under proper conditions. Aubert of Switzerland and Hartmann of Paris maintained that the vaginal method sufficed for both low and high fistulas.

A paper was read by Claude Beclere of Paris on functional uterine hemorrhages. Hysterosalpingography permits differentiation of hemorrhages due to pathologic lesions (from 25 to 30 per cent of the cases) from those of functional origin (from 60 to 70 per cent of the cases). Among the latter, one can identify (a) functional hemorrhages in virgins, (b) those of congenital origin, (c) those due to ovarian infection in young women, and (d) premenopausal disturbances. All are characterized histologically by a benign hyperplasia of the uterine mucosa and radiologically by a dentated aspect of the uterine shadow. In a and b the administration of progestin gives excellent results and in c vaccino-therapy and diathermy are indicated while in d roentgenotherapy is to be used.

French Otorhinolaryngologic Congress

This year's French Otorhinolaryngologic Congress was held October 17-20 at the Paris Medical School under the presidency of Professor Bremond of Marseilles. The evening before the opening of the congress a meeting of the Society for Laryngo-Esophagocopy was held. The first subject of the special reports and general discussion for the congress was the

parent society was "Indications and Results of Intracranial Surgery of the Auditory Nerve." The report had been prepared by Drs. Maurice Aubry and Marcel Ombredanne of Paris. Full credit was given to the work of Dandy, who first showed the value of section of the auditory nerve in Meniere's disease. There is a direct etiologic relation between an adjacent arachnoiditis and an atypical Meniere syndrome. Section of the acoustic nerve presents no technical difficulties but there are certain contraindications, such as the age of the patient, hypertension, a developing otitic condition and an acute anterior meningitis. Of forty-six surgical cases, complete division was done in twenty-five and partial division in nineteen while a tumor of the auditory nerve was removed in two. In the uncomplicated cases, all the operations were successful. Only patients with marked vertigo which has resisted all other forms of treatment should be operated on. There is a chance that this operation will facilitate a more accurate study of the etiology of vertigo and of vestibular physiology.

The second report was on acute inflammation of the hypopharynx in children and had been prepared by Drs. Le Moine, Bloch and Bouchet. Up to the present, this condition has been considered to belong to pediatrics rather than to laryngology, but there appears to be no contraindication to the use of endoscopic methods in both diagnosis and treatment. These severe forms of laryngitis have their origin in the subglottic portion of the larynx, termed "hypopharynx," and involve a very narrow portion in young children, among whom edema can easily occur because of the folds of the mucosa and the many lymphoid structures. This subglottic zone is hypersensitive and easily gives rise to reflexes. These subglottic forms of laryngitis include a type in which spasm predominates, i.e. the stridulous form, an asphyxiating type with marked edema, a localized type with tendency to abscess formation, and an acute fulminant type of laryngitis accompanied by tracheobronchitis in which thick exudates or membranes form which can completely occlude the lumen of these structures. The last named condition has been studied more in the United States than elsewhere because of the more widespread use of broncho-esophagoscopy. The diagnosis can be made by this method but the first problem that presents itself is to distinguish the endoscopic picture from that of a diphtheria or a reaction due to the presence of a foreign body. Low tracheotomy performed at an early period of the condition as recommended by Chevalier Jackson, is preferable to intubation because of the faulty construction of the cannula usually employed. Tracheotomy ought to be followed by aspiration and intrabronchial instillations. The importance of using moist heat and of various forms of apparatus in which oxygen or, better still, a nitrous oxide-oxygen or oxygen-helium mixture was used was emphasized. All children's hospitals should have trained endoscopists attached to their staff to meet such emergencies as acute inflammations of the hypopharynx present. They should also be equipped with the necessary apparatus for physical therapy.

Drs. Hicquet and Scherer of Brussels in a paper on radiography of the larynx with the aid of opaque medium stated that profile views were the best. Dr. Worms called attention to osteosarcomas of the mastoid in young children in which the earliest sign was an increase in size of the mastoid. Dr. Canuut and Gunsett of Strasbourg stated that tomography, i.e. radiography in sections, was very useful in the diagnosis of laryngeal cancer.

Eight personal observations of keratosis of the external auditory canal were reported by Rendu of Lyon. Cited as an example of endolaryngeal cancer by a special technique was that of a paper by Dr. Quinquin of Dijon. Dr. J. Meunier of Paris reported 41 per cent cures following six sittings in seventy-four cases of mastoiditis treated by the use of roentgen rays.

Developments in the Sickness Insurance

New regulations with regard to the admission of physicians to the sickness insurance practice have just been promulgated. For every 600 sick insurance club members a physician will be allowed to practice who has completed at least two years of preparatory service. Permits already granted under the older law are not affected by the new. In the selection from among candidates for the panel practice, preferment is given above all to physicians who have been active for at least two consecutive years at the public health headquarters of the Nazi party and to physicians who have been professionally active for at least one year in military or work service. On the other hand, doctors who served during the World War are no longer given preferment. Mere membership in the Nazi party is no longer a basis for preferment, a candidate must have a record of noteworthy services to the party. German physicians residing abroad who have rendered signal services to Germany or to German science are now as before admitted to the practice under special conditions. Physicians severely wounded in the World War are still accorded consideration. In addition a married candidate comes in for special consideration and the more children he has the greater the likelihood that he will be admitted. Other groups which receive preferment are doctors who have been in insurance practice in the country or in small cities for at least five years and who are seeking posts in the larger cities in order to provide their children with better educational advantages and doctors who have no assured income from property or pensions. No physician is admitted to panel practice if there exist serious personal grounds for rejection, such as addiction to drugs, political unreliability, married status of a woman physician whose family income from insurance practice would not be necessary to the economic security of the family, and simultaneous maintenance of a dental practice. As under the old regulations any doctor is excluded from insurance who is married to a person of non-German or unrelated blood, namely, to one who would previously have been designated "non-Aryan." The national fuhrer of the sickness insurance associations of Germany is empowered to make exceptions in cases which involve so called hybrids but each such case will be decided by this official on its individual merits. Presumably only hybrids of the second class would be considered, namely, persons in whose ascendancy there is but one pair of Jewish grandparents.

It is a well known fact that under the old regulations an important principle had come to be accepted (especially since the standardization of sickness insurance in Germany), namely that the insurance patient like any private patient was permitted (with certain limits) a free choice of physician. Although not all private practitioners were accustomed to treat insurance patients, the roster of the insurance physicians was formidable and accordingly a patient encountered little to prevent his freedom of choice. But this situation has been changed. At the party congress in Nuremberg the national fuhrer of physicians, Dr. Wagner, delimited contemplated restrictive measures on the patient's free choice of a physician. The following is a paraphrase of Wagner's remarks. A change will take place in the immediate future. In order to strengthen the bonds between the family physician and his patients, the insured person must now elect the services of a particular doctor for the period of one year and can consult no other during this time, either for his own illness or for that of the members of his family. Thus is inaugurated a new policy of supervision that affects both the physician and the insured. The insurance doctor has till now received compensation only

according to the number of patients treated and this meant that he had a definite economic interest in the number of sick certificates issued by him. The new legislation introduces a radically different system: the insurance doctor will be paid a certain sum for the care of the insured and the insured's family, an arrangement formerly sometimes applied to family doctors. Consequently the insurance doctor no longer has an economic stake in the number of sickness certificates or the amount of illness but, conversely, it is to his advantage that his patients remain in health, as illness now means only additional work for him without extra compensation.

The foregoing statement of the national fuhrer of physicians is in many respects revealing. His comparison of the new system with that formerly in vogue among family physicians is not exactly fair, since the annual honorarium of the insurance doctor, as envisaged in the new law, must naturally be much smaller than that formerly received by the family practitioner. Of much greater significance is the psychologic aspect of the change, for whereas previously physician and patient could quickly conclude any agreement without the interference of a third party, the ubiquitous Institute of Social Insurance now enters into a sort of partnership with the patients and this anonymous "partner" constantly makes its presence felt. This is the "supervision" mentioned by Dr. Wagner and which, although needed for purposes of administration, is capable of exercising a definite influence on the relationship (or on the psychologic relationship, at least) between doctor and patient. Yet even more important than this and the essential feature of the new policy is the argument with regard to the striking reversal of the physician's material interest, namely, that the doctor will now benefit from the continued health of his patients rather than from their illnesses. Apart from many exaggerations which certainly (consciously or as in most instances unconsciously) had been present, the insurance doctor had become, so to speak, the "advocate" of his patients in their claims against the insurance clubs for any kind of special treatment or medicament. But does not the possibility exist under the new plan with its mentioned displacement of economic interest, that a doctor motivated by the wish to see naught but health may relax his careful observation of insurance patients or, quite unconsciously, become loath to recognize true disease? This possible development has been cautiously urged by other critics of the new plan, but the fuhrer of physicians appears to consider it of less importance than the opposite tendency, which, as he mentioned in his speech, leads the doctor to look everywhere for disease. This problem is thus by no means solved and one can only await a further turn of events.

The organization of the sick insurance has been simplified by a new ordinance that became effective October 1. Henceforth there will be four national associations of sickness insurance clubs: municipal, rural, industrial and guild. All are under the jurisdiction of the national minister of labor. Every sick insurance club must be affiliated with one or another of these national associations. The latter serve the individual clubs in an advisory capacity in matters pertaining to the termination or alteration of contracts with the organized representatives of the medical profession, institutions for the sick, dealers in supplies used by the sick insurance and so on. Furthermore, among other administrative functions the national associations supervise the prompt settlement of all honorariums paid out by the member clubs to the physicians. In future the four national associations will be the only organizations of affiliated insurance clubs, other such organizations (about 100 of which were still in existence October 1) have been dissolved. The new law also provides that no insurance association can any longer represent one-sided interests, as occasionally happened under the old organization.

As reported previously, a comprehensive nationalization of independent insurance clubs has been in progress for quite

some time. In the past, many of these independent clubs ran into financial difficulties and not the least reason for this was their small size which prevented them from maintaining the necessary actuarial balance. As a rule this situation led to increased expenditures that exceeded the income from contributions. The reforms in organization of the sickness insurance, which went into effect in 1933, were chiefly aimed at the creation of larger spheres of activity for weakly functioning and financially embarrassed clubs by consolidation of these clubs with other more solvent clubs. As a result of this program the number of independent clubs declined by around 2,000 during the years from 1933 to 1937, namely, from about 6,550 to 4,600. Most pronounced were the declines in the number of municipal clubs (from about 2,000 to 900) and the guild clubs (from about 800 to 300). As a further result of this reorganization the average premium rate in the municipal clubs dropped from 57 per cent in 1933 to 54 per cent in 1937, in the guild clubs there was a corresponding decline from 49 per cent to 47 per cent during the same period. These reductions were effected without any curtailment of benefits to members. On the contrary, the services of the clubs were able to function more adequately because of the sounder financial position.

The German Substitute for the Nobel Prize

A law was recently passed in Germany, motivated by political consideration and specifically by dissatisfaction with the selection of a Nobel peace prize winner, according to which German citizens are no longer permitted to accept a Nobel prize, and a national prize was created as a substitute (*THE JOURNAL*, April 17, 1937, p. 1354). This new prize has just now been awarded on the occasion of the party congress in Nuremberg. Two physicians were among the prize winners: Professor Sauerbruch, Berlin, ordinarius in surgery, and Professor Bier, the surgeon, now retired. The cash prize was divided between the two men so honored, each of whom received 50,000 marks.

BUENOS AIRES

(From Our Regular Correspondent)

Oct. 20, 1937

Experimental Hypertension

Profs. B. A. Houssay and J. C. Fasciolo, in lectures delivered at the Academia Nacional de Medicina and the Sociedad Argentina de Biología, reported studies on experimental arterial hypertension induced by compressing the renal artery according to the technique of Goldblatt, Lynch and Summerville. In arterial hypertension induced by unilateral compression of the renal artery, removal of the ischemic kidney results in normalization of the blood pressure, which continues normal after the experiment. Implantation of the ischemic kidney and its compressed renal artery, by uniting the renal artery to the carotid artery and the renal vein to the jugular vein in the neck of a dog in hypertension which was recently nephrectomized and treated with chloralose, increases the arterial pressure of the receptive dog within five or ten minutes 40 or 70 mm of mercury up to an approximate high level of 200 mm of mercury. If the grafted kidney is removed hypertension does not diminish but continues high for the first two or three hours after its removal. If the kidney is transplanted in another dog in the same condition as the former, the same increase of arterial pressure is induced in the former as in the latter. The blood pressure of receptive dogs does not increase if the transplanted kidney is normal whether the structure was removed from a normal dog or from a dog in a state of hypertension. Transplantation of both normal kidneys induced intense hypertension only in two dogs and slight hypertension in one. The experiments prove that the ischemic kidney secretes substances that cause permanent arterial hypertension.

New Teaching Chairs

The Escuela de Medicina of Buenos Aires recently lost thirty-eight teaching chairs, and lately chairs have been established for the teaching of semeiology, nutritional disease, renal surgery, history of medicine and puericulture. Profs. R. Izquierdo, Pedro Escudero, M. Balado, J. P. Beltrán and Pedro Elizalde are the appointed teachers. Four physicians were appointed assistant professors to the classes of surgical pathology. The Escuela de Odontología of Buenos Aires increased the teaching chairs from six to sixteen. Discussions are marked on the subject because of the fact that there are neither rooms nor money enough for incurring new expenses. The money allowed for teaching expenses has been cut down, since 1930 to almost half the original amount.

Fellowships

Fellowships have been granted as follows. From the Asociación Argentina para el Progreso de las Ciencias to Drs. Moisset de Espanes, A. Manso Soto, Schwarz and Prosky. They will do special studies on pharmacology and bacteriology in Paris, London and the Pasteur Institute of Paris respectively. The Academia Nacional de Medicina granted the Duvoisin fellowship to Dr. N. G. Foglia, who will work first with Professor Collip of the McGill University in Montreal and then in the United States.

The Comisión Nacional de Cultura granted a fellowship to Dr. Introzzi to study surgery in hypertension and to Dr. J. C. Nuñez to study gastro-enterology in the United States.

The Rockefeller Foundation granted a fellowship to C. M. Pomeroy of Clark University to work in the Instituto de Fisiología of the Faculty of Medicine of Buenos Aires.

Drs. N. Ludueña, J. B. Odoriz and C. A. Tanturi came back home after having made fellowship studies. Dr. Ludueña worked on pharmacology at Oxford, Dr. Odoriz worked on neurophysiology at Oxford and the Rockefeller Institute in New York and Dr. Tanturi worked in the Department of Physiology of the Northwestern University Medical School in Chicago.

Deaths

Dr. Manuel A. Santas, substitute professor of pediatrics of the Faculty of Medicine of Buenos Aires and adviser to the faculty, is dead.

Dr. Miguel Angel Finochietto, head of the ward of practical work in descriptive anatomy of the Faculty of Medicine of Buenos Aires, is dead.

Dr. Ricardo Colon, a fellow of a number of the Academia Nacional de Medicina, died recently at the age of 77.

Marriages

ADLAI STEPHENSON LILLY, Richmond, Va., to Mrs. Sarah Bugg Gholson of Henderson, N. C., October 23.

POTTER A. RICHARDS, Vinton, Va., to Miss Margaret Frances Morrison of Rockbridge County, September 18.

LEO BROWN SKEEN to Miss Frances Elizabeth Ashburn both of Troy, N. C., in Durham, September 13.

THOMAS ADDISON MORGAN, Franklin, Va., to Miss Margaret Virginia Ellis, in Ashland, September 4.

ARAL C. SORENSON, Davenport, Iowa, to Miss Margaret Bagley of Chicago, October 16.

LOUIS C. POSEY to Miss Mamie Lowe Walker both of Birmingham, Ala., October 2.

LEVIN HENRIKSON PEEK to Miss Frances E. O'Brien both of Cherokee, Iowa, October 8.

CHARLES K. PADGETT to Miss Virginia Hoey Smith both of Shelby, N. C., November 2.

RAYMOND V. MCCRAY to Miss Martha Brown both of Vermont, Ark., October 15.

HOMER R. MAULDING, Atlanta, to Miss Thelma Irene Hester, September 26.

Deaths

William Craig Meanor • Pittsburgh, University of Pennsylvania Department of Medicine, Philadelphia, 1895, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, served during the World War, surgeon Beaver Valley General Hospital, New Brighton, Rochester General Hospital, Rochester, Pa., and the Valley Hospital, Sewickley, aged 65 died, September 25, of cerebral hemorrhage

Sinclair Tousey, Garden City N Y, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888 surgeon outpatient department, Roosevelt Hospital, New York, 1891-1900, formerly director and consulting surgeon of the St Bartholomew Clinic and Hospital, author of 'Medical Electricity and Röntgen Rays' aged 73 died, September 25 in the Morrison Hospital Whitefield, N H, of valvular heart disease

Solomon Jones • Danville Ill, Illinois Medical College, Chicago, 1902, past president and secretary of the Vermilion County Medical Society, past president of the Aesculapian Medical Society of the Wabash Valley fellow of the American College of Surgeons, formerly member of the city board of education, on the staff of the Lake View Hospital aged 65, died September 25, of cerebral hemorrhage

John Crego Lester • New York Long Island College Hospital, Brooklyn, 1879 member of the American Otolaryngological Society, fellow of the American College of Surgeons, assistant surgeon, New York Eye and Ear Infirmary, aged 81, died, September 25, in the House of Mercy Hospital, Pittsfield, Mass., of diabetes mellitus, hypostatic pneumonia and hypertrophy of the prostate

Warren Wilson • Northfield Minn, Chicago Medical College, 1889, an Affiliate Fellow of the American Medical Association past president of the Rice County Medical Society, served during the World War, for many years member and secretary of the school board, on the staff of the Northfield City Hospital aged 74 died September 4, of heart disease

Henry Martin Cass, Johnson City, Tenn Vanderbilt University School of Medicine, Nashville, 1900, member of the Tennessee State Medical Association, fellow of the American College of Surgeons, veteran of the Spanish-American and World wars, on the staff of the Appalachian Hospital, aged 62 died, September 13 of coronary thrombosis

Thomas Jefferson Brothers • Anniston, Ala College of Physicians and Surgeons, Baltimore, 1903 fellow of the American College of Surgeons, past president of the Calhoun County Medical Society served during the World War, surgeon to the Garner Hospital aged 57 died, September 1 of coronary thrombosis and arteriosclerosis

William Grosvenor Fulton, Scranton Pa Bellevue Hospital Medical College, New York, 1886 fellow of the American College of Surgeons consulting surgeon, Scranton State and Moses Taylor hospitals Scranton, Nesbitt Memorial Hospital, Kingston and Carbondale (Pa) General Hospital aged 76, died, September 27 of arteriosclerosis

George W Allaman • Atchison, Kan Ensworth Medical College, St Joseph Mo, 1892 past president of the Atchison County Medical Society formerly member of the state legislature, member of the city council and mayor of Atchison on the staff of the Atchison Hospital aged 74, died, September 24, of cerebral hemorrhage

Frederick Ellis Jones, Quincy, Mass Harvard University Medical School, Boston 1897, member of the Massachusetts Medical Society served during the World War formerly health officer, aged 64 on the staff of the Quincy City Hospital where he died, September 29 of chronic interstitial nephritis and mesenteric thrombosis

Peter Drummond, Grant Mich Trinity Medical College Toronto Ont, Canada 1888 Queens University Faculty of Medicine Kingston Ont Canada 1889, member of the Michigan State Medical Society formerly village president and president of the school board aged 70, died, September 24 of coronary thrombosis

Clarence Augustus Shimansky, Sandusky Ohio University of Michigan Homeopathic Medical School Ann Arbor 1898 member of the Ohio State Medical Association aged 62 on the staffs of the Providence Hospital and the Good Samaritan Hospital, where he died September 13 of intestinal obstruction

Leroy Taylor Howard • Lieutenant Colonel U S Army, Hyattsville Md Georgetown University School of Medicine Washington D C 1913 served during the World War

entered the medical corps of the U S Army as a first lieutenant in 1917, aged 48, died, September 30, of arteriosclerosis

Thomas William Smith, Newberry, S C, Louisville (Ky) Medical College, 1891, member of the South Carolina Medical Association, past president of the Newberry County Medical Society chairman of the board of health of Newberry, aged 68, died, September 11, in a hospital at Columbia

Frank Alembert Brayton, Indianapolis, Indiana University School of Medicine, Indianapolis, 1912, served during the World War, associate in dermatology and syphilology at his alma mater on the staffs of the City and Methodist hospitals, aged 47, died, September 20, of heart disease

Jules Louis Prevost, Port Providence, Pa, Temple University School of Medicine, Philadelphia, 1909 also a clergyman formerly lecturer on history of medicine and medical terminology, at his alma mater, at one time a missionary in Alaska, aged 74, died, September 2

John Lee, Detroit Detroit College of Medicine, 1890, formerly assistant professor of medicine at his alma mater, veteran of the Spanish-American War, for many years on the staff of St Marys Hospital, aged 68, died, September 22, of chronic nephritis and myocarditis

Charles William Huff, Jackson, Wyo, Baltimore Medical College, 1912, member of the Wyoming State Medical Society, fellow of the American College of Surgeons on the staff of St John's Hospital, aged 49 died, September 22, at Idaho Falls, Idaho of agranulocytosis

Thomas Henry Hall, Brighton, Ill, Rush Medical College, Chicago, 1884, member of the Illinois State Medical Society, formerly mayor, and member of the board of health, aged 77, died, September 10 of sarcoma of the pelvic bones with metastasis to lungs and other organs

George R Clayton, Monon, Ind, Kentucky School of Medicine, Louisville, 1880, member of the Indiana State Medical Association, for many years member of the school board, health officer, aged 83 died, September 8 at Rensselaer, of carcinoma of the rectum

Pedro G Acosta, Rome, N Y University of Santo Tomas College of Medicine and Surgery, Manila, P I, 1925, for several years resident physician to the Oneida County Hospital aged 36 died, September 28 of chronic interstitial nephritis and cerebral hemorrhage

Marion Blaisdell MacMillan, Milwaukee, University of Texas School of Medicine Galveston, 1898, formerly connected with the U S Veterans Bureau, aged 61, died, September 1, in the Epworth Hospital, South Bend, Ind, of perforated gastric ulcer and peritonitis

William Robert Perdue, West Chester, Pa, University of Pennsylvania Department of Medicine Philadelphia, 1874, member of the Medical Society of the State of Pennsylvania, aged 88, died, September 13, in the Chester County Hospital of chronic myocarditis

Joseph Cameron McClurkin, Evansville, Ind, Bellevue Hospital Medical College, New York, 1880, member of the Indiana State Medical Association, for many years on the staff of St Marys Hospital, aged 84, died, September 18, of cerebral hemorrhage

Arthur Charles Wheeler, Erie, Pa College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893, member of the Medical Society of the State of Pennsylvania aged 68, died, September 4, in Waterford, of paralysis agitans

Alice Catherine Fitzsimmons Lankford, Princess Anne, Md Woman's Medical College of Pennsylvania, Philadelphia, 1904 member of the Medical and Chirurgical Faculty of Maryland, aged 54 was found dead, September 28, of a self-inflicted bullet wound

Ralph Allison Goodner, Anna Ill, Rush Medical College, Chicago, 1888 Jefferson Medical College of Philadelphia, 1891 medical superintendent and managing officer of the Anna State Hospital, aged 72 died September 19, of enteritis and chronic myocarditis

Leo Wesley Chilton, Boise, Idaho University of Minnesota College of Medicine and Surgery, Minneapolis 1904 served during the World War, for many years associated with the Veterans Administration Faculty aged 59 died, September 14

George E Webster, Kingsville, Ohio, Western Reserve University Medical Department, Cleveland, 1880 at one time coroner of Ashtabula County aged 79 died August 22, in the Deaconess Hospital, Cleveland, of hypertrophy of the prostate

Milton H Herbein, Macungie, Pa., Jefferson Medical College of Philadelphia, 1879, member of the Medical Society of the State of Pennsylvania, aged 80, died, September 17, of cerebral thrombosis, arteriosclerosis, chronic myocarditis and nephritis

James Samuel Hess, Mauston, Wis., Barnes Medical College, St. Louis, 1893, member of the State Medical Society of Wisconsin, on the staff of the Mauston Hospital, aged 73, died, September 15, of chronic myocarditis and coronary occlusion

Ord Otterbein Le Master, Sidney, Ohio, Starling Medical College, Columbus, 1902, member of the Ohio State Medical Association, aged 61, on the staff of the Wilson Memorial Hospital, where he died, September 15, of an impacted gallstone

Albert Samuel Wall, Los Angeles, Miami Medical College, Cincinnati, 1890, member of the California Medical Association, past president of the Champaign County (Ill.) Medical Society, aged 76, died, September 9, of diabetes mellitus

Leopold Kaffie, Corpus Christi, Texas, Louisville (Ky.) Medical College, 1903, member of the State Medical Association of Texas, aged 57, died, September 28, in a hospital at San Antonio, of myocarditis and carcinoma of the bladder

William Pierce Fitzgerald, Gerald, Mo., Missouri Medical College, St. Louis, 1887, member of the Missouri State Medical Association, aged 76, died, September 14, of injuries received in an automobile accident and hypostatic pneumonia

David Beaty Frontis, Ridge Spring, S. C., University of Maryland School of Medicine, Baltimore, 1880, member of the South Carolina Medical Association, aged 81, died, September 24, in the Columbia (S. C.) hospital, of pneumonia

William E Stemen, Grosse Pointe Park, Mich., Fort Wayne (Ind.) College of Medicine, 1894, served during the Spanish-American and World wars, aged 67, died, September 12, of aortitis and chronic myocarditis

Charles L Willian, Buffalo, Ky., Kentucky School of Medicine, Louisville, 1889, aged 76, died, September 25, in the Kentucky Baptist Hospital, Louisville, of arteriosclerosis, heart disease and hypertrophy of the prostate

Edward Charles Kauffman, Union, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1901, aged 65, died, September 16, in the Deaconess Hospital, Marshalltown, of coronary thrombosis

Joseph Briggs Murphy, Taunton, Mass., Harvard University Medical School, Boston, 1883, member of the Massachusetts Medical Society, aged 77, died, September 5, at Falmouth Heights, of heart disease

David Gilbert Estes, Athens, Ala., University of Tennessee Medical Department, Nashville, 1901, member of the Medical Association of the State of Alabama, aged 58, died, September 18, of coronary occlusion

Jean Baptiste Archambault, Woonsocket, R. I., School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval at Montreal, 1894, aged 69, died, September 21, of cerebral hemorrhage

John Milton Smith, New Philadelphia Ohio Cincinnati College of Medicine and Surgery, 1880, for many years a member of the board of education, aged 81, died, September 5, of arteriosclerosis and uremia

Don H Hinckley, Chicago, Jenner Medical College, Chicago, 1909, aged 59, died, September 5, in the Victory Memorial Hospital, Waukegan, Ill., of injuries received in a fall from a tree

Walter Q Harper, Los Angeles, Kentucky School of Medicine, Louisville, 1898, on the staff of the Physicians and Surgeons Hospital, Glendale, aged 64, died, September 19, of coronary embolus

Ulric Zwingle Junkermann, Pomeroy Ohio Cleveland-Pulte Medical College, 1913, served during the World War, aged 51, died, September 24, at his home in Middleport, of angina pectoris

Isaac Chase Irish, Bowdoinham, Maine Medical School of Maine, Portland, 1878, formerly member of the school board and health officer, aged 83, died, September 27, of carcinoma of the pancreas

Joseph French Alsop, Prospect Va., University of Virginia Department of Medicine, Charlottesville, 1898, member of the Medical Society of Virginia, aged 85, died, September 4, suddenly

Flora Allison Wright, Tulsa, Okla., Oklahoma School of Medicine, Oklahoma City, 1910, died, September 9, in the Southern Oklahoma Hospital, of tuberculosis

Andrew John Heimark, Fargo, N. D., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, aged 57, died, September 17, of myocarditis

Clarence Garrabrant, Atlantic City, N. J., College of Physicians and Surgeons, Baltimore, 1886, aged 81, died, September 30, in a local hospital of chronic prostatitis and obstruction

John Sidney Hood, Gastonia, N. C., Jefferson Medical College of Philadelphia, 1907, member of the Medical Society of the State of North Carolina, aged 53, died, suddenly, September 14

Cooley S. Ellis, Lonoke, Ark., Louisville (Ky.) Medical College, 1905, member of the Arkansas Medical Society, aged 61, died, September 4, of carcinoma of the stomach and chronic nephritis

Henry A. McIlmoyl, Ogdensburg, N. Y., McGill University Faculty of Medicine, Montreal, Que., Canada, 1900, aged 83, died, September 21, of chronic endocarditis and acute parotitis

Charles Hammond, Topeka, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka, 1897, aged 63, died, September 17, of septicemia and endocarditis

Leinster Duffy, New Bern, N. C., College of Physicians and Surgeons, Baltimore, 1889, aged 79, died, September 20, of cirrhosis of the liver with biliary obstruction

Edwin S. Lothrop, Washington, D. C., Howard University College of Medicine, Washington, 1893, aged 67, died, September 23, of mediastinal tumor and carcinoma

Frederick Stork, Wickliffe, Ohio, Cleveland Homeopathic Medical College, 1903, aged 73, died, September 12, of coronary thrombosis and lymphatic leukemia

Anti Costa Watts, Birmingham, Ala., Louisville (Ky.) Medical College, 1892, aged 67, died, September 12, at his home in Lewisburg, of chronic myocarditis

Charles Joseph Roberts, Berwyn, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1882, aged 80, died, September 3, of myocarditis

Oscar D. Whalin, Chicago, Rush Medical College, Chicago, 1890, aged 71, died, suddenly, September 12, of cerebral hemorrhage and arteriosclerosis

William Garr Shadrach, Culpeper, Va., University of Virginia Department of Medicine, Charlottesville, 1892, aged 61, died, August 12, of cerebral hemorrhage

Harry M. Lincoln, Wilton, N. Y., Albany (N. Y.) Medical College, 1886, aged 79, died, September 24, of carcinoma of the gallbladder with metastasis to the liver

Duff M. Hodges, East Prairie, Mo., University of Tennessee Medical Department, Nashville, 1890, aged 81, died, September 20, of cerebral hemorrhage

Solomon Oliver Mayerson, Chicago, Loyola University School of Medicine, Chicago, 1921, aged 48, died, September 2, of cerebral vascular hemorrhage

Taylor Jirardeau Frierson, Augusta, Ga., Leonard Medical School, Raleigh, N. C., 1902, aged 62, died, September 1, of heart disease and influenza

John Washington Meek, Chicago, Rush Medical College, Chicago, 1881, aged 78, was found dead, September 17, of gunshot wounds of the head

Erly H. Madison, Olean, N. Y., University of Buffalo School of Medicine, 1891, aged 69, died, September 15, of heart disease and arteriosclerosis

John R. Archer, North Baltimore Ohio, Starling Medical College, Columbus, 1887, aged 77, died, September 4, of carcinoma of the stomach

William Holmes Bryan, Pavo, Ga., Atlanta Medical College, 1893, aged 69, died, September 1, of chronic nephritis and arteriosclerosis

George F. Henry, Kelat, Ky., Cincinnati College of Medicine and Surgery, 1879, aged 83, died, September 3, of valvular heart disease

William B. McIntosh, Colfax, Ill., Barnes Medical College, St. Louis, 1895, aged 71, died, September 8, of carcinoma of the prostate

Edwin W. Duncan, Burlington, Ky., Medical College of Ohio Cincinnati, 1885, aged 76, died, September 28, of myocarditis

Thomas S. McCoy, Bradenton Fla., Hospital Medical College Atlanta, Ga., 1910, aged 58, died, September 27, of malaria

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Tru Tablets of Aspirin—Blackstone Mfg Co Newark N J Composition 497 grains of aspirin per tablet For acute rheumatism, gout, sciatica tonsillitis influenza etc Fraudulent therapeutic claims—[N J 25150 August 1936]

Bron Ki—Bron Ki Co Columbus Ohio Composition Eucalyptol and terebinthine Fraudulently represented as a cure for bronchitis and kindred disorders—[N J 25381 October 1936]

Tipona Tablets—Hi Test Laboratories doing business as Mison Laboratories and Tipona Co Cleveland Composition Essentially phenol phthalein (1 grain per tablet), caffeine and desiccated thyroid (about ¼ grain per tablet) Fraudulently represented to prevent or eliminate fat to produce muscle bone and sound flesh correct glandular disorders resist disease germs etc The claim No drugs of Any kind was also fraudulent—[N J 25385 October 1936]

Nurse Brand Blood Purifier—DeFree Co Holland Mich Composition Essentially potassium iodide and extracts of plant drugs including a laxative with alcohol sugar and water On the label the plant drugs were declared to be Honduras sarsaparilla dandelion root burdock root and clover tops Fraudulent therapeutic claims—[N J 25387 October 1936]

Sanacaps—Jessie Rogers trading as Osan Products Co Chicago Composition Baking soda tartaric acid and a small amount of chloramine T Fraudulently represented as a germicide and a cure for leul or rhea and inflammation—[A J 25394 October 1936]

Rogers' (Dr) Relief Compound—Jessie Rogers trading as Osan Products Co Chicago Composition Aloe a turpentine oil resembling oil of savin and iron sulfate coated with sugar and calcium carbonate Fraudulently represented as a remedy for female disorders—[N J 25394 October 1936]

Obeayne (Formerly Medogyn Hygienic Vaginal Jelly)—Dayton Laboratories Inc Dayton Ohio Composition Essentially water glycerin gum tragacanth lactic acid a quinine compound hydroxyquinoline and small amounts of resorcinol and zinc compound Fraudulently represented as a cure for leukorrhea vaginitis and gonorrhea as a prophylactic for gonorrhea and syphilis and a germicide Fraudulent therapeutic claims—[V J 25405 October 1936]

Grabli's (Dr) Prescription No 1313—Hi Test Laboratories doing business as the Mison Laboratories Cleveland Composition Tablets containing 771 grains of cinchophen each For rheumatism neuritis arthritis uric acid etc Fraudulent therapeutic claims—[A J 25405 October 1936]

BP Prescription—DeFree Co Holland Mich Composition Essentially potassium iodide extracts of plant drugs including a laxative with alcohol sugar and water For impure blood Fraudulent therapeutic claims—[N J 25406 October 1936]

Lur Eye Lash Developer—Lur Eye Products Inc New York Composition Essentially 13 per cent of volatile oils including wintergreen and thymol in a base of white petrolatum For developing eyelashes relieving bloodshot or inflamed eyes and granulated lids Fraudulent therapeutic claims—[V J 25409 October 1936]

Blackstone's Tru Laxative Bromides Quinine Cold Tablets—Blackstone Mfg Co Newark N J Composition Essentially acetanilid (14 grains per tablet) quinine dihydrobromide (0.96 grain per tablet) and aloe For the gripe colds coughs etc Fraudulent therapeutic claims—[N J 25415 October 1936]

Tru Lax—Blackstone Mfg Co Newark N J Composition Essentially phenolphthalein (17 grains per tablet) and chocolate which was worm eaten and contained wormy excreta For sour stomach jaundice bad breath headache etc Fraudulent therapeutic claims—[N J 25419 October 1936]

Lubrol—Atlas Laboratories Akron Ohio Composition Water boric acid (19 per cent) Irish moss glycerin starch lactic acid and a small amount of oxyquinoline sulfate Fraudulently represented as a germicide and a remedy for leukorrhea cervicitis vaginitis etc—[A J 25415 October 1936]

Knifers Tonic (Formerly Dr Neuffer's Lung Tonic)—McMurray Drug Co Abbeville S C Composition Essentially creosote a chloride alcohol (17 per cent) and water For coughs bronchial asthma etc Fraudulent therapeutic claims—[A J 25420 October 1936]

Pneumo Nox—Willard Products Co Greenville N C Composition Essentially volatile oils including menthol and eucalyptol in petrolatum For bronchial and lung troubles Fraudulent therapeutic claims—[N J 25421 October 1936]

Wiltone—United Distributors, Inc Louisville Ky Composition Essentially epsom salt salicylic acid and water flavored with cinnamon Fraudulently represented as a cure for headache chronic maluria rheumatism impure blood etc—[N J 25423 October 1936]

Krispy Krumbs—Better Wheat Foods Co and Denton Rogers Logan Utah Composition Essentially wheat containing a large amount of bran with little if any flaxseed present Misbranded in the statement 100% Whole Wheat whereas it was not Fraudulently represented as a remedy for stomach ulcers kidney and liver disorders rheumatism diabetes etc—[N J 25851 January 1937]

Exsereo Antiseptic Deodorant Disinfectant—Exterminating Service Co Inc, Pittsburgh Composition Essentially soap water coal tar neutral oils and phenols Fraudulently represented as an antiseptic and disinfectant and an effective treatment for hair and scalp a douche and a remedy for chapping itching and minor wounds—[N J 25805 January 1937]

Gyptol—Folsom Extract Co Inc Lynn Mass Composition Soap phenols coal tar neutral oils and water Fraudulently represented as an antiseptic if used according to directions and a pain remedy—[N J 25806 January 1937]

Sanderson's (Dr P C) Indian Herbs of Joy and Blood Cleanser—Aschenbach & Miller Inc Philadelphia Composition Ground crude drugs including aloe cinnamon and ginger Fraudulently represented as a blood cleanser health promoter and a treatment for liver disorders dyspepsia rheumatism malarial fevers etc—[N J 25819 January 1937]

Sulfo Kresol Tabs—Ehrhart & Karl Inc Chicago Composition Oxyquinoline sulfate (slightly more than ¼ grain per tablet) and milk sugar free sulfur and cresol were not found Misbranded because of misleading name fraudulently represented as a cure for inflammatory conditions septicemia and ulcerated throat—[N J 25802 January 1937]

Cafumet Herb Tea—Joseph E Meyer trading as Indiana Botanic Gardens Hammond Ind Composition Dried plant material including senna leaves juniper root cascara bark fennel seed licorice mallow root leaves flowers and unidentified woody material Fraudulently represented as a remedy for aching joints nervousness all disorders due to constipation including cancer etc—[N J 25812 January 1937]

Kloria—Kloria Co Fort Wayne Ind Composition Chloramine and salt For most skin diseases inflammations sore throat inflamed eyes and dandruff Fraudulent therapeutic claims—[N J 25807 January 1937]

Red Cross Brand Periodic Pills—Ernest E Schneider trading as Snyder Products Co Chicago Composition Iron sulfate plant material including a laxative and a preparation of ergot coated with sugar and chalk Fraudulently represented as a female regulator—[N J 25826 January 1937]

Voxol—John H Vernet trading as Voxol Laboratories Oak Park Ill Composition Essentially a fixed oil containing volatile oils including eucalyptus and menthol For sinus disorders asthma pneumonia diphtheria etc Fraudulent therapeutic claims—[N J 25825 January 1937]

Kavatone Soft Mass Pills—Gray's Medicine Co, South Bend Ind Composition Essentially plant drugs including a laxative For gall bladder and liver troubles etc Fraudulent therapeutic claims—[N J 25810 January 1937]

Hygena—Lee W Wiggins trading as Hygena Laboratories Atlanta Ga Composition Essentially epsom salt boric acid and ammonium alum perfumed with volatile oils including peppermint Not antiseptic as claimed Fraudulently represented as a remedy for sore foot inflammation wounds hemorrhoids leukorrhea etc—[A J 25827 January 1937]

Congoin—Congoin Co Los Angeles Composition The leaves of yerba mate a caffeine bearing plant Fraudulently represented as supplying necessary minerals lacking in foods and as a remedy for mental strain acid stomach neuritis rheumatism etc—[A J 25828 January 1937]

An Idin—Hygienic Supply Co Loudonville N Y Composition Essentially an iodine compound incorporated in petrolatum and perfumed with wintergreen For sciatica enlarged glands arthritis etc Fraudulent therapeutic claims—[N J 25834 January 1937]

Snyder's (S P) Tablets Prescription No XX—Ernest E Schneider trading as Snyder Products Co Chicago Composition Iron sulfate plant material including a laxative and a minute amount of alkaloid coated with sugar and chalk Fraudulently represented as a remedy for obstinate and abnormal delayed eases of menstruation—[N J 25826 January 1937]

Pfeiffer's Sore Throat Remedy—S Pfeiffer Mfg Co St Louis Composition Water glycerin ammonium chloride potassium chlorate and sodium benzoate with wintergreen flavor For tonsillitis hoarseness ulcerated or mouth etc Fraudulent therapeutic claims—[A J 25836 January 1937]

Kompo Bile Salts Tablets—Kompo Co Atlanta Ga Composition Small proportions of iron calcium and magnesium compounds bile acid extracts of plant drugs and phenolphthalein (approximately ½ grain per tablet) Fraudulently represented as a remedy for headaches indigestion liver and kidney disorders gallstones heart trouble cancer etc—[A J 25829 January 1937]

MENTAL DISTURBANCES FROM ATROPINE OR NOVATROPINE GIVEN TO SUBJECTS UNDER THE INFLUENCE OF INSULIN

To the Editor—Though Dr J P Quigley's article (*THE JOURNAL*, October 23, p 1363) is of value in offering pharmacologic evidence for the clinical effectiveness of belladonna derivatives in idiopathic hypoglycemia, his "warning against the administration of atropine preparations" in these conditions, based on observations interpreted as delayed synergistic action, is not justified. Aside from the facts that idiopathic hypoglycemia, most frequently, is not due to hyperinsulinism, and that the transitory beneficial action of belladonna derivatives on hypoglycemic manifestations would naturally be followed by an aggravation of the preceding condition as the effect of the drug wore off, doses of atropine or novatropine respectively greater than $\frac{1}{400}$ grain (0.65 mg) or $\frac{1}{25}$ grain (25 mg) under no circumstances can be considered "moderate." When average doses of belladonna derivatives by mouth are not infrequently followed by dryness and dilatation of the pupils, surely subcutaneous doses of atropine as large as $\frac{1}{50}$ grain (18 mg) or $\frac{1}{20}$ grain (35 mg) of novatropine may be expected to be followed, not infrequently, by symptoms of atropinism, even in conditions not characterized by hypoglycemia.

JOHN F QUINLAN, M.D., San Francisco

PORTABLE APPARATUS FOR PROLONGED ARTIFICIAL RESPIRATION

To the Editor—Dr Flagg in a communication published in *THE JOURNAL*, October 9, page 1216, writes concerning patients with poliomyelitis requiring respirator treatment but who are in communities where respirators are not available. He suggests laryngoscopy, intubation and insufflation of oxygen under pressure as a practical means of tiding such patients over this fatal period. He further states that "injuries directed to personnel interested in the care of such cases reveals that the technic has not been used and is not being used."

A portable apparatus for prolonged artificial respiration was devised (Brahdy, Leopold, and Brahdy. *M B Am J M Sc* 178 405 [Sept] 1929) and used at the Willard Parker Hospital before the present type of respirator became available. When artificial respiration in a respirator is advocated it should be stated that this treatment sometimes has serious and fatal sequelae (Brahdy, M B and Lenarsky. *Maurice J Pediat* 8 429 [April] 1936). Patients with mild or even moderate respiratory embarrassment usually can be tided over their critical period by sedation and reassurance. This phase of the management of poliomyelitis was discussed in an editorial in *THE JOURNAL* (Dec 23 1933, p 2053).

M BERNARD BRAHDY, M.D. Mount Vernon N Y

GONORRHEAL ARTHRITIS IN INFANCY

To the Editor—May I direct the attention of Drs S J Hoffman and Maurice Schneider (*Gonorrheal Sepsis in an Infant* *THE JOURNAL*, October 30 p 1447) to a report by M B Cooperman (*Gonorrheal Arthritis in Infancy* *Am J Dis Child* 33 932 [June] 1927). This report covers an epidemic of gonococcal infection involving sixty-seven (of 182 new-born infants exposed). Of the fifty-eight infants, fifty-three developed joint infection, the remainder had meningeal involvement. Forty-four (of the fifty-three) boys, twenty-three girls were affected. One infant developed gonorrheal arthritis.

Otherwise first symptoms were not noted until the eighth or ninth day after exposure (i.e., after birth), elevated temperature, toxic rash, polyarthritis and superficial abscesses. On the eleventh day, diarrhea with purulent stools, and vaginitis were noted. The only positive blood culture obtained, and this after ten days' incubation, was in a boy with polyarthritis. Five boys and three girls had a gonococcal proctitis with positive rectal smears. In no case was there evidence of heart, kidney or lung involvement, and there were no deaths.

A bacteriologic study of a purulent stool early in the epidemic might have disclosed the identity of the organism until the rampage ten days before its initial identification in joint exudates. Writers seem to be minimizing the rectum as a portal of entry for the gonococcus. This possibly is applicable also to the umbilical vessels.

NATHANIEL HURWITZ, M.D., Philadelphia

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY CONSULTING AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

LEUKOCYTE COUNT IN ALLERGY

To the Editor—I should like information on the value of the leukocyte count in detecting allergic reactions to foods. How great is the rise in a normal person after ingestion of 8 ounces of milk after a fifteen hour fast? How great a leukopenia signifies anything in an allergic reaction when given the inciting food? Do you know of any reliable test or article that can be obtained at this time? Should a food that causes an increase (from 100 to 400 per cent increase in the leukocyte count) be taken from a diet list? An increase seems to occur and is (thirty minutes) followed by an ill feeling, on the part of the patient.

M D Arkansas

ANSWER—Early French investigations on food anaphylaxis demonstrated that an acute reaction to allergenic food was accompanied by a pronounced fall in the leukocyte count (Widal and Joltrain). Vaughan believes that this leukopenic response to allergenic foods is a characteristic reaction in food allergy and may be employed in the identification of suspected foods. He believes that a drop of 1,000 or more below the fasting level following the ingestion of the test food is usually indicative of allergy. Three serial counts are made at intervals of thirty minutes following the ingestion of food. A rise in the leukocyte count is of no diagnostic significance.

Two questions have been raised concerning the reliability of this method. First, it has been suggested that blood counting cannot be performed accurately enough for a drop of 1,000; second, the leukocyte count to be significant. Second, the work of several investigators has suggested that normally, even without food ingestion, there is too wide a natural fluctuation in the leukocyte count level to make a drop of 1,000 significant. Recent work, however, appears to have invalidated the greater part of the criticisms. Ponder, Saslow and Schweizer (1931) have shown that, if sufficient cells in the chamber are counted (800) the normal blood leukocyte count remains reasonably constant. Bryan, Chastain and Garrey (1935) have shown that even with a smaller number (10 square millimeters on the cover slip) a chamber with blood diluted 1:20 counting may be accurately made to within 700 cells. Garrey and Bryan (1935) have reviewed the physiologic factors which influence the leukocyte count. These must be adequately controlled in the determination of the leukopenic index.

The existence of a normal digestive leukocytosis is a well known question. Garrey and Bryan conclude from a review of the various contributions on the subject that there appears to be evidence of a postprandial leukocytosis of low degree but that it is due to factors other than digestion itself, such as increased hydrochloric acid in the stomach, distention of the stomach, the presence of hot or cold substances in the organ.

Details concerning the technic of blood counting are given by W R Chastain, L and Garrey. *W J* 113 416 (Oct) 1935.

Details of the technic of the leukopenic index determined by Vaughan Warren. *J Lab & Clin Med* 21 1 1936.

Physiologic fluctuation in the true leukocyte count. Garrey W E and Bryan W R. *Physiol Rev* 15 1935.

ARTERIOSCLEROSIS OBLITERANS IN FEET

To the Editor—I have a patient a man aged 81 whose only abnormality is peripheral vascular occlusion of the toes and feet. There is no evidence of arteriosclerosis of other vessels as eye vessels and blood pressure and urine are normal. His principal complaint is painful red burning feet worse at night. There is no phlebitis and considering his age I consider it to be due to arteriosclerosis rather than to Buerger's disease. I should like information on the use of Padutin in this type of case. There is no intermittent claudication. Who makes Padutin and where is it available? Is it expensive? What is the present status of the passive vascular exercise machines in this type of case? Who makes these machines and what is their approximate cost?

M D Indiana

ANSWER—Burning distress in the feet may well be a symptom of decreased arterial circulation caused by arteriosclerosis. However, this symptom may result from other causes, such as peripheral neuritis. It is assumed that the correspondent's diagnosis of arteriosclerosis obliterans is based on the absence of or diminution of pulsations in the chief arteries of the lower extremities, on reduced temperature of the skin of the feet, and on abnormal rubor with dependence and abnormal pallor with elevation of the feet. However, even when such conditions are observed, the distress may be due either to ischemic neuritis produced by the diminished arterial circulation or to some other cause unrelated to the diminution of circulation. Padutin, which is an insulin free pancreatic extract manufactured by the Winthrop Chemical Company, 170 Varick Street, New York, is not useful in this particular situation but is of value only in the relief of the symptom intermittent claudication. There is no unanimity of opinion relative to the use of the alternating suction and pressure apparatus in treating arteriosclerosis obliterans. It is, however, quite apparent that the enthusiasm for machines of this type has waned decidedly since they were first placed on the market. Whether or not the correspondent's patient would be benefited by treatment with one of these machines could be determined only by trial. Approximately 100 hours of treatment should be given each extremity. The subject is reviewed by E V Allen and G E Brown in *THE JOURNAL*, Dec 21, 1935, page 229. Machines can be bought from the Cincinnati Scientific Company of Cincinnati, the Warren E Collins Company of Boston, the J H Emerson Company of Cambridge, Mass., or the Burdick Company of Milton, Wis. The cost varies with the type of machine purchased but most of them cost in the neighborhood of \$500.

MERCURIAL DIURETICS

To the Editor—1. In a patient with obstinate edema from progressive heart failure a mitral valve lesion and myocardial degeneration what would be considered absolute contraindication to the use of the mercurial diuretics? What is the influence of nephritis and low kidney function? 2. Has it been ascertained or is it accepted that salyrgan is less toxic than novasurol?

M D Arkansas

ANSWER—1. Although the clinical information given does not suffice for an accurate etiologic diagnosis of the cardiac disease, it may be stated that heart failure per se is certainly not an absolute contraindication to the use of the organic mercurial diuretics. It is assumed, however, that the patient has already received an adequate amount of digitalis, has been on a cardiac diet and has otherwise been given the full benefit of the accepted treatment for heart failure. It is generally agreed that patients with severe myocardial insufficiency should not be given mercurial diuretics before the ordinary measures have been instituted and found to be inadequate in ridding the patient of edema. Contraindications to the use of mercurial diuretics are acute or active (hemorrhagic) chronic glomerulonephritis, low renal function of any origin, e g, less than 30 to 40 per cent of the average normal urea clearance, inability to concentrate the urine to a specific gravity of 1.018 or higher, or an excretion of less than 25 to 30 per cent of phenolsulfonphthalein in two hours after intravenous injection of the dye, stomatitis ulcerative lesions of the gastro intestinal tract, or severe diarrhea known idiosyncrasy to the mercurial compound, acute or subacute hepatitis with jaundice, cachectic or marantic states, leukemia in the later stages, severe anemia especially if due to or associated with intestinal hemorrhage, recent coronary thrombosis or severe angina pectoris, failure to obtain diuresis, or the development of oliguria, increased microscopic hematuria or any other signs of mercury poisoning, after the injection of trial doses of the organic mercurial.

2. In spite of considerable investigation on men and laboratory animals, the comparative toxicity of salyrgan and merbaphen (novasurol) has not been clearly established. The clinical reports indicate that merbaphen is much more toxic than salyrgan. In fact the latter drug has almost entirely replaced the former in clinical use during the last few years. It should

be noted, however, that salyrgan was introduced after enough experience had accumulated in the use of merbaphen to teach physicians the proper indications, contraindications and dosage of this powerful drug. Hence fewer toxic reactions have resulted from the use of salyrgan. Experiments on rabbits showed only slightly more toxicity of merbaphen than of salyrgan (Johnstone, B I *J Pharmacol & Exper Therap* 42:107 [May] 1931). Both compounds produced renal lesions typical of poisoning with inorganic mercury. It is possible that the organic radical of merbaphen, apart from the mercury, may be responsible for some toxicity in man. There is no clearcut evidence at present.

LEUKORRHEA

To the Editor—A white woman aged 26 single weighing 105 pounds (48 Kg) has had a leukorrheal discharge for the past three years beginning with a slight discharge before and after each menstrual period. At that time she was examined by a physician smears were taken and there was no evidence of gonococci being found. She was given 10,000 potassium permanganate douches for approximately four months which did not seem to help at all. She was advised by another physician later to take Davegan tablets followed by a cleansing douche. This treatment was taken for a few months with no help. She went to another physician and was given quinine capsules as vaginal suppositories for *Trichomonas vaginalis*. This also did not help. Again on the advice of another physician she was advised to take diluted solution of sodium hypochlorite which seemed to help best of all. The patient came under my care approximately three months ago. At that time the Wassermann reaction was negative, catheterized urine specimens were negative, the red blood cell count was 4,500,000, the hemoglobin 90 per cent, the white blood cell count 14,400, polymorphonuclears 78 per cent, segmented forms 73 per cent, nonsegmented 75 per cent, lymphocytes 16 per cent, monocytes 6 per cent, and eosinophils 1 per cent. Three other white blood counts ranged from 12,000 to 15,000. There has been no elevation of temperature. On pelvic examination a medium sized speculum was inserted with comparative ease. There was first degree retroversion. The uterus was normal in size and consistency with no evidence of any erosions. There was a seropurulent discharge coming from the cervix. The entire vaginal vault was filled with a white foamy purulent discharge resembling that of *Trichomonas vaginalis*. The adnexa were completely normal. The vagina was red and inflamed with a very slight evidence of excoriation. Smears for gonococci were negative. Cultures taken on Sabouraud's medium were negative, agar nutrient medium 2 Hay bacillus colonies, beef of agar medium negative, bacteriophage culture medium negative, nutrient broth medium Hay bacillus. The patient was kept in bed for two weeks and given cleansing douches of salt and soda without any relief. April 9, 1937, the vaginal wall was washed with tincture of green soap. This was painful for the patient and on the following day when she came back for another treatment, the discharge had become white, thick and creamy. The vaginal wall was much too irritated for another treatment of this sort. Menstruation is regular with a profuse discharge and slight pain for the first two days. Kindly suggest diagnosis and treatment. Would you advise cauterization of the cervix?

M D Florida

ANSWER—*Trichomonas vaginalis* is mentioned a number of times in the query but there is no definite statement as to whether or not this organism was actually found. The simplest and cheapest way to find this out is to examine a drop of the discharge without any staining. A drop of saline solution is added to a drop of the vaginal discharge and the mixture is examined first with the low and then with a high power lens of a microscope. If trichomonads are present, they will be detected with ease because of their motility. The slide should also be studied for Monilia, especially because of the change in the discharge to a white, thick, creamy consistency after treatment with green soap. The appearance of the vagina may be due to excessive and perhaps rough treatment.

The cervix should by all means be treated if it is certain that the seropurulent discharge originates from this structure and is not simply some of the vaginal discharge deposited on the cervix and on the external os. One of the most satisfactory ways to treat the cervix is by means of the nasal tip electric cautery.

Not infrequently in cases in which it is difficult to cure a persistent leukorrheal discharge there is some constitutional disturbance. In some cases the administration of thyroid is distinctly helpful. However, before thyroid is given, it is advisable to have a basal metabolism study.

The treatment of *Trichomonas vaginalis* vaginitis is unsatisfactory chiefly because recurrences are common. Since the vagina is badly irritated at the present time it is best to use a dry form of treatment. With great gentleness the vaginal discharge should be removed with cotton pledgets. Then a powder should be blown into the vagina. Satisfactory results are being obtained with sodium methylmercaptosulfonaminohydroxyphenylarsenate, as recently described by Bland and Rakoff (*Am J Obst & Gynec* 32:835 [Nov] 1936, abstr *THE JOURNAL*, January 9, p 145). Biskind (*Lancet* 2:1049 [Nov 9] 1935) reported good results following the use of solutions of basic phenylmercuric nitrate. Silver picrate also is recom-

mended. It Monilia is found it can readily be eliminated by the use of gentian violet.

The physician should discuss with the patient the matter of cleansing herself after bowel movements. Many women use an upward sweep from the anus toward the vagina. If trichomonas gains access to the vagina from the rectum, as some individuals believe, such upward sweeping motions may produce reinfections. Patients should be instructed to use a sweeping motion directed away from the vagina and toward the sacrum.

CAUSES OF ACNE

To the Editor—In mild cases of acne vulgaris the following seems to be the sequence of events: 1 The skin becomes soft both subjectively and objectively. 2 The skin then becomes relaxed or toneless. 3 At this time it will be noticed that the pores are enlarged and comedones are apparent. 4 The skin assumes a blotchy appearance and the various forms and phases of the eruption appear. The basic change that seems to have occurred is the relaxation or loss of tone of the skin. If at any time some procedure is carried out that will prevent this relaxation or increase the tone of the skin the steps will reverse themselves and the skin tend to clear except for the comedones or pustules that have developed too far. Three procedures that tend to do this are: 1 Application of medicaments containing sulfur, resorcin and so on. 2 Application of ultraviolet rays or sunshine. This must be intense enough to cause a sunburn and the effect is of value only when this reddening sunburn is present in other words when and while the patient actually feels the burn. After the skin becomes tanned the treatment is much less effective or entirely ineffective. Here it will be noted that when the treatment is effective the patient has the feeling that his skin is drawn tight across his face. Examination will reveal the pores to be very small. Under the optimal conditions this treatment will change the course of events and the appearance of the skin over a period of six hours. 3 Application of cold—rubbing ice on the face exposing the face to cold winds and the like. Here also the patient will have the feeling that the skin is drawn tight on his face and it will be noted that the pores of the skin are small. However, under optimal conditions this is not as effective as the ultraviolet rays or sunshine. It is this last observation about which the present communication is concerned—the prophylactic and therapeutic effect of cold on acne vulgaris and its relation to the physiologic cause of the condition. It would seem that the accuracy of this observation might be determined in part at least by determining the prevalence of acne vulgaris in the arctic and antarctic circles. (I have never seen a picture of an Eskimo with this condition.) Some of the statements that I have made are subject to dispute but they are stated dogmatically to develop the point more easily.

E. W. GROVE, M.D., Gainesville, Ga.

ANSWER—The discussion of the factors in the genesis of acne on the basis of the correspondents' observations is interesting.

The soft, relaxed, toneless skin seen in acne is usually a part of the sluggishness that exists in some of these affected persons at the age of adolescence because of sedentary habits, dietary indiscretions and certain underlying endocrine factors. Any application that tends to combat or alter these factors is usually associated with some degree of improvement. The application of stimulating local applications containing sulfur and resorcinol, the use of erythema doses of ultraviolet rays, or exposure to the sun tends to have a stimulating effect with associated increase in circulation of the skin of the face. The application of cold, because of its astringent effect and subsequent hyperemia, produces the general effects described. Contrast applications with hot and cold water associated with brisk rubbing of the face, have long been a part of the regimen of therapy in the hands of many.

The type of life led by the inhabitants of the arctic is one of great physical activity in which the people alternate between fast and famine. The diet includes meat and fish of various types obtained from the uninhabited regions, which is usually eaten raw. "Contrary to general opinion the Eskimo eats relatively little fat or blubber" (Thomas W. A. Health of a Carnivorous Race: A Study of the Eskimo, THE JOURNAL, May 14, 1927, p. 1559).

A vigorous life with exposure to the elements and the lack of certain excesses in diet is an important contributory factor in the absence of an acne soil in the Eskimo.

GASTRO PHOTOGRAPHY

To the Editor—I would appreciate your opinion of the Gastro Photo which has been exhibited at the annual session of the American Medical Association and also some of the state meetings.

W. L. CASLER, M.D., Marquette, Mich.

ANSWER—Many attempts have been made to develop a direct, anatomic diagnostic procedure for gastric lesions. Three methods exist at this time: (1) the x-ray relief method with compression; (2) gastroscopy; and (3) gastrophotography. The x-ray relief method developed by Heilpern and Schindler has been shown to be of great value especially in the diagnosis of gastric

ulcer and tumors, but the smaller lesions, especially the diffuse forms of gastritis and small superficial ulcerations, often cannot be demonstrated in this way. Gastroscopy developed slowly from 1868, became a safe procedure with the use of the flexible gastroscope in 1932. The results are excellent. The method should not be confused with open tube procedure such as esophagoscopy. Gastrophotography was initiated first by Lange of Munich in 1898 and reached a certain perfection with the construction of the "gastrophotor," by Back and Heilpern of Vienna in 1929. A small photographic camera, containing eight films which are exposed through 'pinhole' openings without lenses, and a lamp are introduced into the stomach. A quick exposure of the eight films is made by pressing a button and thus illuminating the mucosa by the powerful lamp. The results of the three methods have been compared by three gastroscopists, Henning, Moutier and Schindler. All three agree on the great value of the x-ray relief and gastroscopic methods, both of which are considered indispensable and supplementary to each other. On the other hand, these three authors unanimously reject gastrophotography for a number of reasons, the most important of which are: (a) the pictures often are blurred; (b) a real orientation within the stomach is impossible; and (c) the important color changes in the mucosa are not reproduced in the black and white film. Gastrophotography apparently is carried out in a routine way only by Heilpern in Philadelphia, Heilpern in Vienna, Bernay in Lyons and Hofmann in Buenos Aires, while the other two methods are carried out in many hospitals and clinics all over the world.

SURGERY IN AMYOTROPHIC LATERAL SCLEROSIS

To the Editor—A patient with diabetes always under control for seven years developed two years ago a spinal lesion situated just above the sixth dorsal rib and manifested by great pain in the extremities. All tests (x-ray, lipid injection, Queckenstedt's test) were negative and failed to reveal the exact nature of the trouble—whether tumor or hemorrhage. Three months ago she began to display all the symptoms of hyperthyroidism: pulse 120 and the basal metabolism reaching plus 60 per cent. Simultaneously the neurologist changed his diagnosis from a spinal lesion to probable amyotrophic lateral sclerosis. Compound solution of iodine and two months of rest brought the pulse down to 100 and the basal metabolism to plus 35 per cent. A thyroidectomy, or at least a lobectomy, was considered but it was opposed on the ground that patients with spinal disease, especially amyotrophic lateral sclerosis, cannot withstand the strain of even the most minor operation and usually die. Accordingly as a last resort two x-ray treatments were administered. Although the metabolic rate fell to plus 26 per cent the causal connection between the x-ray treatments and the drop in basal rate is questionable. The problem of the feasibility of a lobectomy has arisen again. Can you throw any further light on the risk involved? The patient who is about 60 years old but little if any weight prior to the onset of the hyperthyroidism and has lost about 30 pounds (13.6 Kg.) since. If an operation is decided on what anesthetic in view of the inadvisability of using a spinal anesthetic would you suggest?

SAUL MEBEL, M.D., New York

ANSWER—There is no known evidence that amyotrophic lateral sclerosis is a contraindication for surgical intervention. In this case the only contraindication would be the diabetes. If the latter was well controlled, surgery could be done. Amyotrophic lateral sclerosis is one of the most common causes of true bulbar palsy. When bulbar palsy exists, any anesthetic other than local would be a potential danger because in bulbar palsy the circulatory, respiratory and deglutition functions are defective and anesthesia might make them worse. If the patient has no signs of bulbar palsy, local nitrous oxide gas, ether or ethylene anesthesia may be used.

METHYL CHLORIDE POISONING

To the Editor—What is the latest treatment for poisoning from methyl chloride in refrigerators? M. D. ASTORIA, O.

ANSWER—The injury produced in methyl chloride poisoning may represent a profound asphyxiation if the exposure is severe or it may be substantially the same as that caused by methyl alcohol if the patient escapes or survives asphyxiation. In asphyxiation, the patient should be removed from further exposure and if respiration has ceased but the victim is still alive, artificial respiration should be carried out. The use of oxygen with or without the addition of 5 or 7 per cent carbon dioxide may be indicated. The objective in this phase of the treatment naturally is to remove from the lungs all possible methyl chloride.

Methyl chloride taken into the body is decomposed into methyl alcohol and hydrochloric acid. Hydrochloric acid combines with mineral salts in the blood to form such compounds as sodium and potassium chlorides which are relatively innocuous and as a result these salts do not enter into general poisoning. The treatment for poisoning from

chloride then becomes the same as for poisoning from methyl alcohol. A primary objective is to combat acidosis. In acute situations, intravenous administrations of an alkalizing solution are in order. Administration by mouth and by rectum of similar substances are advised. Enemas of 3 per cent sodium bicarbonate with 5 per cent dextrose solution have been utilized. At times sedatives may be required because of convulsive attacks, but more often respiratory and cardiac stimulants may be applied. The chief points of injury are likely to be the kidneys, the liver and the central nervous system, including the optic nerves. For their protection, treatment should be directed to the prompt elimination of the methyl alcohol, which is discharged from the body much less readily than ethyl alcohol.

ABDOMINAL CRISES

To the Editor—A German aged 50 well developed and of good nutrition for the past thirteen years has had recurring attacks of pain in the right upper quadrant of the epigastrium. These pains start gradually and increase in intensity for about four to six hours until they are severe and then gradually subside. They are gone in from eighteen to twenty-four hours leaving him in perfect health again. While the pains are present they are constant and are relieved only by opiates. The interval between attacks has always been well defined. At first it was about twenty days. A few years ago it changed to eleven days and at present it recurs at nine day intervals. The patient can predict the day on which it will come. During the years of his illness he has been seen by numerous gastro-enterologists. He has been roentgenographed and given gastric function tests. All tests were negative. The Wassermann reaction was negative. Nevertheless on one occasion several years ago a surgeon was convinced that the trouble lay in the gallbladder. He did a cholecystectomy. The pains continued as before. Physical examinations show no tenderness or other abnormalities. The man was told by several gastro-enterologists that nothing could be done for him. Have you any suggestions to offer?

M D New York

ANSWER—It is impossible to arrive at an exact diagnosis from the evidence presented. In spite of the fact that the Wassermann reaction was negative, it might be interesting to know the results of the Kahn reaction of the blood and the serologic reaction in the spinal fluid. These abdominal crises are not at all uncommon in syphilis and malaria and often have been known to occur as abdominal manifestations of epileptiform seizures. In the latter connection, these attacks are frequently relieved by putting the patient on a ketogenic diet and giving small doses of phenobarbital. Other than that there are no suggestions to be made.

NONSPECIFIC URETHRITIS

To the Editor—Two evenings ago a patient had had intercourse with his wife for the first time in two weeks. He used a condom, known as "Gold Tex." Shortly after the emission he noted some burning within the urethra. The next day it was worse. That evening (the one following the intercourse) he noted some white discharge. This was greater in amount the following day. Examination showed pus on the end of the penis. The first glass was cloudy with shreds the second clear with shreds. Microscopic examination showed many pus cells with no organisms on two successive days. He stated that he had not had extramarital contact during the past year. There is no previous history of infection. He had used four of the same type prophylactics two weeks previously without difficulty. This type condom has what looks like yellow or gold powder at the tip (inner). After three days treatment the pus disappeared. Although the first glass appeared slightly cloudy with shreds burning on micturition had ceased. Are there any records of a nonspecific urethritis caused by Gold Tex condoms? Does this not appear more of a nonspecific than a gonorrheal urethritis?

M D Connecticut

ANSWER—If the gonococcus could not be demonstrated in this case, it is evidently a case of nonspecific urethritis. Rubber condoms may be the cause of dermatitis, balanitis and nonspecific urethritis. The people who develop these conditions are those who are sensitive to rubber. Such cases have been reported in the literature (Obermayer, M E. *Eczema Due to Hypersensitivity to Rubber*, *Arch Dermat & Syph* 17:25 [Jan] 1933; Rattner, Herbert. *Dermatitis of the Penis from Rubber* *THE JOURNAL*, Oct 12, 1935, p 1189).

IODIDES IN TUBERCULOSIS—RAISING ARMS IN TUBERCULOSIS

To the Editor—Two questions in tuberculosis. 1. Is the aversion to iodides sound or is it based on the questionably analogous action in gummas? 2. Some men forbid patients to raise their arms above the head. Is this sound or a fetish based on faulty anatomical reasoning?

M D New York

ANSWER—1. Considerable doubt has arisen in the minds of physicians as to whether iodides in usual dosage have any deleterious effect on the lesions of pulmonary tuberculosis. At one time the iodides were used extensively in the diagnosis of pulmonary tuberculosis that is when tubercle bacilli could not be recovered from the sputum large doses of iodides were

administered, following which in some cases tubercle bacilli appeared in the sputum. The conclusion was drawn that the iodides broke down the lesions and liberated bacilli. As these drugs serve as expectorants by increasing and liquefying the secretions in the bronchial tree, it seems probable that they only resulted in liberation of mucus and other materials from the region of the lesion in which bacilli could be demonstrated. The fear of the administration of iodides to tuberculous patients has definitely decreased in the past few years.

2. There is also considerable doubt whether forbidding patients to raise their arms above the head has any sound basis. The most that can happen by bringing the arms to this position is a slight elevation of the ribs to which the pectoral muscles are attached but this probably is not as great as, or certainly no greater than, the elevation of the ribs on ordinary inspiration. Like a number of beliefs with no scientific basis, coincidence was probably responsible for this one. For example, a patient may have a pulmonary hemorrhage begin while the arms are above the head and the conclusion is immediately drawn that it was this position which resulted in the hemorrhage, when in reality it would have occurred regardless of the position of the arms.

DERMATITIS FROM HAIR DYE

To the Editor—A middle aged woman about nine years ago and again recently developed a dermatitis following the use of hair dye to blacken her hair. The first time both eyes were swollen and the scalp was red but the condition did not last long. The last time within twenty-four hours after visiting a beauty parlor her scalp began to itch and burn and her eyes began to swell which progressed to complete closure of both eyes. This condition lasted about twelve hours. During this time her scalp was red and edematous the edema and redness extending below the hair line and down the back of the neck. I saw her again yesterday, ten days after the dye was applied and the scalp in spots and all around the hair line extending over the temples and the back of neck was cracked and there were dry crusts between with serum pouring from the cracks. I have used hot physiologic solution of sodium chloride and calamine lotion after an initial shampoo to begin with. The eyes are still a bit puffy but otherwise the physical examination including urinalysis was negative. She does not recall the brand of the hair dye she first used, but the last was called Cloral Hair Dye made or distributed from Danville Ill. She is anxious to avoid a repetition of this experience and I should like to know what was probably the causative drug or drugs. Her general health is good and she shows no allergic symptoms.

M D Indiana

ANSWER—The common offender in hair dyes is paraphenylenediamine, an efficient black dye. No information as to the composition of "Cloral" dye is obtainable. The patient to avoid future trouble, will have to stop dyeing her hair. Hairdressers cannot be depended on to know what is in the dyes, and paraphenylenediamine is so much more satisfactory than any other dye that she is sure to have it used again if she continues having her hair dyed.

VARICOCELE

To the Editor—Kindly outline the present day treatment of varicocele. Is operation performed as much as formerly? If so what is the type of operation? To what extent is varicocele a bar to employment in industry? Is it now considered a forerunner of hernia?

M D Minnesota

ANSWER—A varicocele is not operated on frequently. It occurs in adolescence and its symptoms, which may be to a certain extent mental, usually subside in a few years. Varicocele usually occurs on the left side but it is occasionally bilateral and when associated with a long dependent scrotum may produce some disability in an active person. In certain industries requiring considerable activity or standing it would be considered a handicap. This would depend on the degree of enlargement of either the varicocele or the scrotum and the symptoms produced, together with the type of work demanded.

Varicocele is not considered as predisposing to hernia. The development of a varicocele in an older man on the left side should lead one to suspect pressure or neoplasm in the region of the kidney involving the internal spermatic vein, which empties into the left renal vein. Operation for varicocele should never be done at the same time as a hernia operation unless one understands the danger of postoperative atrophy of the testicle from pressure about the remaining veins in the inguinal canal after resection of a portion of the varicose veins. Atrophy is not likely to occur when the operation is limited to the resection of a short segment of only a part of the varicose veins and approximation of their ends to aid suspension of the testicle. The lower portion of a long redundant scrotum may be resected at the same time, but great care should be taken to control bleeding. Following operation there should be no physical disability or handicap in heavy labor.

ECTHYMA OR FACTITIOUS DERMATITIS

To the Editor—Can you offer any suggestion as to the possible cause of a peculiar lesion on a school girl aged 15 years which first appeared to be a blister from a burn then looked mildly infected and was dressed with moist antiseptics but took nearly a month to form a firm crust? This after five weeks appears as a punched out nearly healed ulcer three fourths inch across with a black hard slightly depressed covering. She had a similar smaller lesion on the forearm a year or so ago which ran a similar course and the same indefinite history of a burn to account for it. She is in good health and has no skin disease of any kind. The only examination was of the urine which was negative for sugar, albumin, and casts or cells. PAUL W. VANMETRE, M.D., Rockwell City, Iowa.

ANSWER—The lesion described suggests the diagnosis of ecthyma. The possibility of a dermatitis factitia (self-induced eruption) must also be considered.

Treatment of ecthyma consists in removal of the crusts and the application of 3 per cent ammoniated mercury to the base of the ulcer. Daily painting with 3 per cent aqueous solution of gentian violet is also effective. The description of the origin of the lesion strongly suggests the possibility of an external irritant as a causative factor while this irritant may result from contact, the possibility of dermatitis factitia in a girl of 15 deserves consideration. Close observation and the use of a fixed occlusive dressing should rule this out.

MENIÈRE'S DISEASE

To the Editor—I am suffering from Meniere's disease. I had the first attack some twenty odd years ago. It lasted an hour or so and was relieved by a narcotic. Since then it has come about once or twice a year. For the last three weeks it has been with me day and night. I have a constant roaring in my left ear. I am deaf and cannot move my eyes without holding on to something for support else I fall. Please help me. All the remedies suggested by Nebraska specialists have not benefited me. I am 76 years old. MD Nebraska.

ANSWER—There are at least two types of treatment for Meniere's disease, medical and surgical. The medical treatment of his condition is well described by Madelaine R. Brown (*THE JOURNAL*, April 3, p. 1158). The surgical treatment consists of resecting the vestibular branch of the eighth nerve. This operation is especially recommended by Dandy. While there is some dissenting opinion as to the efficiency of surgical intervention, in this particular instance with the symptoms as severe as described, and granted that the diagnosis is correct and that the treatment so far is modern resection of the vestibular portion of the eighth nerve under local anesthesia would appear to be a proceeding that offers the most hope and with no undue risk, even considering the age of the patient.

IODIDES IN RESPIRATORY INFECTIONS

To the Editor—Will you render me a critical opinion regarding the use of iodides in the treatment of acute respiratory infections? There is a tendency on the part of many physicians to use calcium iodide (calcidin), sodium iodide, organiodin, hydriodic acid and the like during the acute phases of respiratory infections. Is this sound therapy? Some investigators seem to feel that iodine may increase edema and dissolve nature's protective barriers and that its use should be withheld until the afebrile period when it may aid in promoting absorption of the residue. I have felt that iodine may be harmful if not judiciously used. MD California.

ANSWER—It is perfectly correct that iodides are not suitable in acute stages of infections of the upper respiratory tract as they are likely to aggravate existing congestion and irritation. They are even charged with the tendency possibly to produce glottis edema when given in such cases. It is in subacute and most especially in chronic conditions that iodide is so very useful.

ATROPHY OF TESTIS

To the Editor—I am 27 years of age. Five years ago a herniotomy for a right sided inguinal hernia caused complete atrophy of the right testicle. Six weeks ago a herniotomy on the left side resulted in an epididymo-orchitis. At the present time the left testicle is slightly smaller than it was prior to operation is extremely hard and is not tender even to excessive pressure. What is the prognosis as to atrophy? If it does atrophy what treatment surgical or medical will prevent or alleviate the results of castration? MD Massachusetts.

ANSWER—Since there are varying degrees of postoperative atrophy of the testicle which is rarely bilateral one cannot predict the extent of loss of function without further studies on the presence of hormone and permanent under these conditions.

Atrophy of the testicle with following a traumatic or infectious etiology the interstitial cell concentration should not occur and the

following involve testicular

At the meeting of the Chicago Society of Internal Medicine, January 25, Fred C. Koch reported a rapid method for quantitative extraction of the sex hormones in normal men and women.

The presence of an epididymitis would temporarily and perhaps permanently prevent the passage of spermatozoa even in the present.

One should search for spermatozoa and, if absent for some time following a preexisting epididymitis, surgical anastomosis of the efferent ducts of the testicle or the lobules of the epididymis to the ductus deferens on that or even the opposite side might be performed to short circuit an obstructed segment. Spermatozoa can be found above it at operation or by aspiration of a spermatocele.

DANGERS OF BUTYN IN URETHRA

To the Editor—E. B., aged 40, colored, was admitted to the hospital for treatment of acute retention due to multiple urethral strictures. General physical examination was entirely negative otherwise. Attempts to catheterize with metal and rubber catheters were in vain and there was considerable trauma attendant on such attempts. However, the patient succeeded in voiding following the use of prolonged sitz baths. The following day a large amount of 4 per cent butyn (10-15 cc) was injected with some force into the urethra and a bougie was inserted but could not be made to pass the final stricture. On the next day immediately following a hot sitz bath an hour long the injection of 1 drachm (4 cc) of 4 per cent butyn resulted almost immediately in convulsions of a generalized clonic type which subsided only to be resumed again in a few minutes. Breathing became increasingly difficult, the lungs filling with a moisture and the patient died in less than five minutes. The blood nonprotein nitrogen immediately after death was 29 mg. and spinal fluid also withdrawn immediately after death showed no cells or globulin and the Kahn and Wassermann reactions were negative. Permission was not obtained for a postmortem examination. Please let us know your opinion of this case. MD.

ANSWER—Butyn is more toxic than certain of the other local anesthetics, the fatality in this case, however, should not be attributed to butyn any more than to another local anesthetic that might have been administered. The Council on Pharmacy and Chemistry and *THE JOURNAL* have warned against the use of local anesthetics in the presence of trauma many times. The circular issued by the Abbott Laboratories and accepted by the Council contains the following statement: "IN GENITO-URINARY SURGERY When trauma exists the use of any local anesthetic is contraindicated."

ATOPIC ECZEMA

To the Editor—I have under my care a child aged 2 years who has had an eczema-like skin eruption almost since birth in the region of the elbows and in both inguinal regions. On physical examination the patient is a perfect specimen of health. All laboratory examinations have been negative. The patient comes from healthy stock with a history of allergy on the mother's side. A thorough skin testing of the child with all material available shows very strong reactions to the different kinds of nuts. While the patient has never eaten according to the parents who are very careful and intelligent. Could this chronic eczema have anything to do with the child's sensitiveness to nuts? If not what would you advise as to the proper procedure in treating this condition? MD Kansas.

ANSWER—With the hereditary, allergic background, and an eruption of "eczema-like" character, this case is most probably an atopic eczema. Even though the patient does not eat nuts, the presence of related nut substances in vegetable fats (margarine, coconut oils, and the like) may be a source of nut substances. The complete elimination of anything that may contain nuts or their derivatives in view of the patient's positive reaction must be assured. A regimen with careful diet elimination should be instituted. Soothing local application, ultraviolet exposures and dicalcium phosphate by mouth together with vitamins A and D, constitute a valuable adjunct to other management.

HEMOSTATICS IN HEMORRHAGE

To the Editor—Will you please inform me as to the value of fibrinogen (Cutter's) or similar products in the control of hemorrhage in the lung caused by injury to the chest in an automobile accident? What is the opinion as to the value of calcium chloride intravenously in a case to arrest hemorrhage? The patient prior to the accident was perfectly well, young adult.

ANSWER—Pickering and Hemmingway demonstrated that question that hemostatics definitely shorten the coagulation time of shed blood. This does not prove, however, that the reabsorption of shed blood is of increased value in closing bleeding vessels. In fact, Graham makes no mention of the use of drugs in the care of intrathoracic hemorrhage resulting from trauma. It is well established that in the normal healthy person, loss of blood itself decreases coagulation time and that drugs are of relatively

insignificant value. Although coagulation of blood depends on the action of calcium ions on prothrombin, producing thrombin, there is ample mobile calcium in the normal person so that additional calcium is unnecessary. Intravenous injection of calcium salts carries with it some danger of unfavorable cardiac action.

Transfusion of blood from a suitable donor is the best treatment in such cases, as it provides human coagulating substances in addition to fluid volume and erythrocytes.

CALCIUM DEPOSITS IN TISSUES

To the Editor—A patient while confined to a hospital was given an intravenous injection of calcium chloride in the arm by an attending intern. The solution went outside the vein and infiltrated the surrounding superficial and deep tissues. After the inflammatory reaction subsided the result was an ugly red scar and multiple lumps of hard calcareous deposits in the tissues. Will you please inform me as to whether there is a way to dissolve the calcium lodged in the tissues and if there is a possibility of its being absorbed in time.

M D Washington

ANSWER—No satisfactory method has been devised for successfully dissolving adventitious calcareous deposits in the soft tissues. Resorption over a long time is possible, but encapsulation is the more common method of foreign body segregation—another reason for the failure of solvents.

The treatment advised after accident is multiple stab punctures and small incisions as soon as possible, attempting to massage the chemical irritant out of the tissues followed by hot applications of magnesium sulfate. Injection of salt solutions to dilute the chemical is not practical, since the original route of the infiltrating calcium chloride solution cannot be retraced. In addition, the mechanical edema further embarrasses the normal attempts at resorption. In the late stages, after scar and nodule formation, plastic surgery is the only resort.

LATE TREATMENT OF BURNS

To the Editor—A patient who was severely burned about the face and hands—second and third degree burns—has had complete epithelization but still a great deal of redness in the burned area. Since the termination of the wax dressings I have been using olive oil and hydrous wool fat locally. The burn is now eight weeks old. What would you suggest to keep the skin soft? Can anything be done to reduce the redness or will this persist until the skin becomes thicker? Some time ago you published a formula for a scarlet red ointment to stimulate epithelization. Will you please repeat this?

M D Pennsylvania

ANSWER—Redness in the healed area following second and third degree burns has a tendency to disappear in time. Keeping the skin soft with olive oil and hydrous wool fat tends to improve the general condition of the superficial scar tissue and the epithelium. Compresses of boric acid solution applied several hours daily have a tendency to reduce the incidence of local infections which may occur in small fissures. X-rays should not be used in an effort to hasten the disappearance of redness in such areas. There is a difference of opinion as to the value of X-rays in the treatment of keloids. Some dermatologists and radiologists consider them of great value. When used, the treatment should be carefully supervised. Scarlet red is usually applied as a 5 per cent ointment.

GOLD BRIDGEWORK TURNING BLACK

To the Editor—A patient employed as a domestic is apparently in good health but complains that gold bridgework recently applied turns black rapidly. What are the possible causes of such a condition and how may it be remedied?

M D New York

ANSWER—The 'gold' bridgework is probably made of a low carat gold. It may be remedied by the use of a higher carat gold.

ZINC IONIZATIONS FOR VASOMOTOR RHINITIS

To the Editor—What is the clinical value of zinc ionizations for vasomotor rhinitis?

M D New Jersey

ANSWER—Zinc ionization has been recommended for vasomotor rhinitis, and while there are favorable reports there are also many disappointments. Recently reports have appeared from men of good standing indicating that the method may be a severe one, its results are not specific, they depend on the production of local changes of a caustic type in the nasal mucous membrane and very late unfavorable after-effects are still to be looked for.

Book Notices

Cunningham's Text Book of Anatomy Edited by J C Brash M A MD FRCS Professor of Anatomy University of Edinburgh and E B Jamieson MD Lecturer on Anatomy University of Edinburgh Seventh edition Cloth Price \$10 Pp 1 506 with 1 247 illustrations New York & London Oxford University Press 1937

In thirty five years this book has gone into the seventh edition The first three editions, 1902-1909, were prepared under the editorship of D J Cunningham, the next three editions under the editorship of Arthur Robinson, and the present edition under the editorship of Drs J C Brash and E J Jamieson The retirement of the previous editor, Professor Robinson, has entailed a change in certain sections of the book, especially Professor Robinson's own chapters on human embryology and the blood vascular and lymphatic systems, which have been revised by Dr Brash, who has also revised the introduction to the book Thus and the retirement of Prof J T Wilson necessitated two new contributors, Prof R D Lockhart of the University of Birmingham, who took over the chapter on myology, and Prof A B Appleton of the University of London, who takes over the chapter on the ductless glands Since only six years has elapsed since the previous edition was published, substantial changes were necessary in only a few sections The whole book, however, has been revised and where necessary changed to comply with the present views and methods in the teaching of anatomy There are many new illustrations A series of plates has been introduced with photographs of the living body showing the effects of muscles in action, and many roentgenograms illustrating the structure and growth of the skeleton and the position and form of the organs in the body Also the revision of the Basle Nomina Anatomica, which was approved by the Anatomy Society of Great Britain and Ireland in 1933, has been introduced The revision in nomenclature is not a sweeping one, however, and much of the apparent change is only a freer translation of the Basle Nomina Anatomica into English than has been used heretofore A glossary preceding the introduction shows what changes have been made in the nomenclature T Wingate Todd, professor of anatomy at Western Reserve University School of Medicine, Cleveland, again has prepared the chapter on the respiratory system and is the only contributor from the United States The book continues to be well adapted to the needs of both practicing physicians and medical students

Clinical Electrocardiography By Sir Thomas Lewis MD FRSc DSc The Lecturer in Charge of Department of Clinical Research University College Hospital London Sixth edition Cloth Price 8s 6d Pp 128 with 109 illustrations London Shaw & Sons Ltd 1937

The first edition of this popular work—a most welcome pioneer volume it was—appeared in 1913 The present edition shows almost no change from the fifth of seven years ago, there are the same number of pages in this edition as in that of 1930 and in the fourth edition of 1928 One familiar figure, however, on page 6, with the hands and left foot immersed in jars, has been replaced by one showing the more modern and simpler method of attaching the electrodes by means of cuffs The last four pages, on the electrocardiogram in coronary artery thrombosis, have been rewritten, bringing this subject more nearly to date It may be of interest to note that the statement at the foot of page 28 concerning the origin of certain anomalous electrocardiograms remains as it was written seven years ago 'Which of these two types represents the human leuogram and which the dexuogram has developed into a matter of debate I therefore leave the curves unidentified with right or left ventricle, and later in this book treat the forms of extrasystole similarly Actually it is at present a matter of little practical consequence to which ventricle the beats are assigned' Some readers will feel disappointment at the unwillingness of the author to express his opinion on this matter which has been so much discussed as also at his omission of any consideration of leads, e g lead 4, other than the conventional three leads This attitude, however, is in line with the plan of the book, which is to avoid topics that Sir Thomas regards as still unsettled or the subject of controversy In spite of these omissions and of some others that have to

do with the more recent developments in electrocardiography, and in spite of the minimal amount of change from the previous edition, the work still remains one of the best guides for the practitioner who desires help in trying to understand the clinical significance of the electrocardiogram As has been so often remarked, Sir Thomas is a past master in his ability to write clearly and tersely

Cancer and Diet with Facts and Observations on Related Subjects By Frederick J Hoffman LL D The Biochemical Research Foundation of the Franklin Institute Philadelphia Cloth Price \$5 Pp 767 Baltimore Williams & Wilkins Company 1937

This book is divided into five parts, not including a group of appendices The first part deals with the dietary theories of cancer, as the author says, it is a review of the statements of "more or less competent" authors on the question of the possible dietary or nutritional influence in cancer causation treatment and control The second part, which is devoted to the modern diet, deals with the author's hypothesis that essential errors underlie the modern diet of civilized races, depending chiefly on modified foods from international sources" As a result it is felt that "far reaching changes in bodily functioning and metabolism are introduced which, extending over many years, are among the causes or conditions predisposing to the development of malignant new growths" The third part deals with cancer metabolism, the fourth with dietary facts concerning cancer patients The fifth contains a general summary and conclusion Under surgery the index lists only two items, namely, surgical failures and operations ineffective Nothing is said of x-rays in the index or of roentgenology Radioactive substances and radium and acid reaction are listed in the index but only a line or two in the text is devoted to either The whole book, therefore, is devoted to expanding an argument, namely, that diet is principally responsible for cancer The book cannot be recommended either as a dispassionate study of diet and cancer or as in any way a well balanced book on cancer Such volumes do nothing to advance knowledge By their approach to the subject they actually impede progress by creating a certain amount of support for charlatans who have been exploiting ideas of dietary causation of cancer for many years

Common Neuroses of Children and Adults By O Spurgeon English MD Clinical Professor of Psychiatry Temple University Medical School Philadelphia and Gerald H J Pearson B A MD Assistant Professor of Pediatrics Temple University Medical School Philadelphia Cloth Price \$3 50 Pp 320 New York W W Norton & Company Inc 1937

As stated in the authors' preface, "this book is an attempt to bring together under one cover material which is so voluminous and so widely scattered as to be with difficulty accessible to the student and practitioner of medicine" The authors not only accomplish their purpose but do so in a clear, concise and well organized manner The Freudian concepts of the dynamics of personality formation and the development of personality aberrations are presented in simple language The neuroses of children and adults with which the physician most commonly deals are described in a systematic fashion Any practitioner interested in these conditions cannot afford to be ignorant of the psychoanalytic approach to them To date, and probably for a long time to come, nowhere will he find this information as thoroughly and carefully presented as it is in this book It must be clearly understood that all the material is presented according to psychoanalytic theories and principles of psychiatry Any one who is unacquainted with psychoanalytic literature and thought will at first reading find it difficult, if not impossible, to accept much of that which the work includes For example, in the discussion on some of the phobias, a great deal of gravity is attached to many minor manifestations As every one knows, fear is an emotional pattern common to the behavior of all children In most instances the source is not difficult to uncover The unconscious fear of castration may be a source of fear of animals in isolated cases, but it would seem that a previous experience of a nip on the leg by a too aggressively sadistic puppy is a much more frequent and logical cause This is not really a defect of the book but an example of psychoanalytic approach with which the average physician will take issue A criticism that might be offered concerns the dogmatism with which the authors discuss treatments of

the neuroses. According to them, psychoanalysis offers the only solution to most of the problems. Since the book is intended for practitioners and students of medicine, the portions on therapy are rather discouraging. Practitioners of psychoanalysis may find the subject matter somewhat elemental for their purpose, but even they will find much that is of value in the material collected from the recent contributions in the field of child psychiatry. Many orthodox psychiatrists will reject this work because of their refusal to accept psychoanalytic theories, but even the most resistant of these psychiatrists will find in this work much that is new and interesting, if not helpful. The authors have avoided any controversial issues with formal psychiatric techniques, except in the last chapter, entitled "Preparation for Psychiatric Work." Herein are set forth the requirements for certification by the American Board of Psychiatry. Following this the authors point out that the important preparation in psychiatry will come "through a knowledge of human psychology and psychopathology which can be acquired only through a study of one's own emotions and their accompanying ideation and behavior and the emotions and resulting ideation and behavior of others."

The Alimentary Factor in Disease. By MAX H. KUCZYNSKI, MD, D.Sc. Pathologist to the Ministry of Public Health of Peru. Second edition of Studies on Nutrition. Paper. Price 3 guilders. Pp. 130. The Hague. G. Naef. 1937.

This is a curious book and one that is based on a good deal of observation and thinking. The author has worked in many parts of the world on a number of the virus diseases such as encephalitis and yellow fever, also on trypanosomiasis and some of the avitaminoses. Always he has been interested in the fact that the nutrition of an animal and its supply of vitamins influence the type of its reaction to infection. He has found also that the nutrition of an animal can affect its sensibility to roentgen rays. In studying yellow fever he was impressed by the fact that the state of nutrition of the monkeys used as experimental animals had much to do with determining whether or not they survived the infection, and this accounts probably for differences in the mortality rates reported by different investigators. Such differences in nutrition account also for peculiar differences in the reactions of individual animals to inoculation with trypanosomiasis. Kuczynski was interested also in the percentage incidence of gastric ulcers seen in animals given different types of diet and then infected with the virus of encephalitis. In children with poliomyelitis he was impressed with the relation between the amount of physical work done and the incidence of paralysis. The book is hard to review partly because each chapter deals with a different disease and partly because the scores of observations recorded are not always well strung on the thread of the author's thought. The text is at times incomprehensible perhaps partly because of a poor translation but with all this the book is thought producing and every young experimentalist who is starting out to work on animals should look through it and should keep in mind the facts which it brings out.

Une forme cérébrale de la cholestérinose généralisée (type particulier de lipose a cholestérine). Par Ludo van Bogaert, Hans J. Scherer et Emilie Epstein. Paper. Price 45 francs. Pp. 183 with 61 illustrations. Paris. Masson & Cie. 1937.

This is the most recent monograph on cholesterol lipodosis. In the introduction it is stated that Ludwig Pick and Emil Epstein classify the diseases of lipid metabolism into three groups which have as a common character deposits of lipids and fatty substances and which have a special characteristic determined lipid. These are the kerales or cerebroside of Gaucher's disease, the phosphatide of Niemann-Pick's disease and the cholesterol lipodosis characterized by the presence of cholesterol and its esters. This includes Schüller-Christian's disease. The authors also speak of a fourth group including progressive hypodystrophy, adiposogenital dystrophy and hypophysial obesity. The first chapter is a discussion of the actually known lipodosis. The second discusses the clinical facts of this disorder and the importance of the clinical aspect in this entity. The third chapter deals with the anatomical and histopathologic study of the disease. The fourth chapter takes up the biochemical aspects of the fatty deposits and the chemical changes up to a

physiopathologic outline of this disorder. The work is done in a clear and critically analytic. It has a large bibliography. It should be available to all pathologists, neurologists, internists and pediatricians.

Practical Methods in the Diagnosis and Treatment of Venereal Diseases for Medical Practitioners and Students. By David Lees, DSO, MA, DPH. With the following contributors: R. Cranston, Low, MD, FRCP, Consulting Physician for Skin Diseases, Edinburgh Royal Infirmary; William R. Logan, MD, FRCP, DPH, Bacteriologist, Edinburgh Royal Infirmary; and R. C. L. Bachelor, MA, MD, FRCP, Director of Department of Venereal Diseases to Edinburgh Royal Infirmary and Edinburgh Corporation. Third edition edited and revised by F. Lees, MB, FRCP, Assistant Medical Officer for Venereal Diseases to Edinburgh Royal Infirmary and Edinburgh Corporation. Cloth. Price 1. Pp. 608 with 93 illustrations. Baltimore. William Wood & Company. 1937.

This publication is in reality a handbook on the clinical management of the venereal diseases prepared for the general practitioner. The third revision is an improvement on the previous excellent work of the late David Lees. That much of the clinical experience on which the book is based was acquired at the Royal Infirmary in Edinburgh is evidenced by the subchapter on gonococcal diseases of the skin, which includes a concise but vivid description of keratoderma blennorrhagica. The schedule of treatment for early syphilis recommended by the Committee of Experts on Syphilis and Cognate Subjects of the Medical Organization of the League of Nations is the scheme of choice of the authors. In the description of regional syphilitic lesions the inexperienced student may be misled by a description of an interesting but rare patient with chancre of the conjunctiva. It is also to be regretted that additional space was not devoted to a more thorough presentation of flocculation tests in the serologic diagnosis of syphilis. The well known preference of British workers for the complement fixation procedure in the serodiagnosis of syphilis probably explains the latter omission. Like most of our British colleagues, the authors have a relatively high regard for the efficiency of complement fixation tests in the diagnosis of gonorrhea. The standards of cure laid down for gonorrhea are interesting and should be a valuable aid to the clinician.

Obstetric and Gynecologic Nursing. By Frederick H. Falls, M.D., F.A.C.S., Professor of Obstetrics and Gynecology, University of Illinois College of Medicine, and Jane R. McLaughlin, B.A., R.N., Superintendent of the Department of Obstetrics and Gynecology Research and Educational Hospital, University of Illinois College of Medicine. Cloth. Price \$3. Pp. 492 with 83 illustrations by Charlotte S. Holt. St. Louis. C.V. Mosby Company. 1937.

In line with the trend in medical education in this country, the authors have combined the subjects of obstetrics and gynecology in one book. Also in accordance with present custom in the preparation of books for nurses, this book represents the combined effort of a physician and a nurse, both of whom are leaders in their field. The book is well written and its thirty-four chapters contain the essential facts which nurses should know about obstetrics and gynecology. The value of the book is greatly enhanced by the illustrations (one is repeated) which are highly instructive. Even though the book does not contain as much information as some other books on obstetrics for nurses, it will nevertheless admirably serve the purpose for which it was written.

Curioterapia in dermatologia. Parte generale. Principi fondamentali della curioterapia. Le trasformazioni radioattive. Basil biologiche. Azione delle varie irradiazioni sulla pelle (Alfa Beta Gamma). Parte speciale. Technica curioterapica nelle varie dermatosi. Dal Prof. Vincenzo Palumbo, direttore Istituto radioterapico Italiano. Pp. 36 lire. Pp. 87 with 76 illustrations. Belluno. Casa editrice Libreria A. Salvador. 1937.

In this little volume Palumbo discusses the value of radium in the treatment of diseases of the skin. The general part of the book takes up the physical foundations of radium therapy, the radioactive transformations, the biologic basis of radium therapy and the action of alpha beta and gamma radiation on the skin. In the special portion of the book the technical aspects of the radium treatment of various dermatoses are treated. The excellence of the results that may be obtained in correct treatment is shown by many photographs of patients. In no sense can this book be regarded as an exhaustive treatise rather it constitutes a brief setting forth of established facts.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Optometry Practice Acts Federal Court May Not Enjoin Enforcement of Injunction Issued by State Court

—The superior court, Mecklenburg County, N. C., enjoined Benjamin Ritholz and others, doing business as the National Optical Stores Company, from practicing optometry in North Carolina or from furnishing any kind of material or apparatus for ophthalmic use without a written prescription from a person, other than an employee of the defendants, licensed to practice optometry or medicine in North Carolina. Ritholz and the other defendants in the superior court then instituted an action in the federal district court, middle district, North Carolina, against the state board of examiners in optometry, the governor, the attorney general, and the sheriff of Mecklenburg County, to restrain the enforcement against Ritholz and the others of (1) the provisions of the North Carolina optometry act and (2) the terms of the injunction issued by the superior court.

The National Optical Stores Company, according to the court, was engaged in the manufacture of eyeglasses, lenses and frames in the city of Chicago. It possessed no license to practice either optometry or medicine in North Carolina. The superior court found that Benjamin D. Ritholz, Samuel J. Ritholz, Morris I. Ritholz, Fannie Ritholz, Sylvia Ritholz and Sophia Ritholz, trading as the National Optical Stores Company, had offices in Charlotte, N. C., and that they employed in those offices one Dr. L. H. Coffey, at a salary of \$45 a week, that the defendants through their agents, advertised in newspapers and by radio that they would sell complete glasses for \$3.45 and guaranteed satisfaction, that a large number of persons who made affidavits responded to these advertisements by going to the offices of the defendants, but none of them were able to purchase glasses for the sum stated but on the contrary most were required to pay several times that amount; that several of the persons who furnished affidavits found their glasses completely unsatisfactory and in some instances the glasses were, according to the affidavit of a doctor of medicine who specialized in the treatment of the eyes, positively injurious to the eyesight of the persons who had purchased them. The superior court further found that the examination of the eyes of persons who purchased glasses from the defendants was made for the most part by Dr. L. H. Coffey who was licensed to practice medicine in North Carolina but that in some instances he had been assisted in making the examination of eyes by persons licensed neither as optometrists nor as doctors of medicine. No separate charge was made for such examinations, but the glasses were sold for a price which included the examination of the eyes. The examinations were made by Dr. Coffey by the use of a trial frame into which glasses were fitted and no other instrument of any kind was used by Dr. Coffey. When glasses were sold, apparently the prescriptions were sent to the offices in Chicago and the glasses sent from there to the North Carolina office. The superior court also found as a fact that one G. P. Sayers, another employee of the National Optical Stores Company in its North Carolina offices, sold or attempted to sell, furnish, replace or duplicate lenses, frames and mountings, and replaced them by ordering them from the Chicago office without a written prescription from persons authorized under the laws of North Carolina to practice optometry or medicine and that this constituted the practice of optometry by the company.

In this case, said the federal district court, the state court held that the method of doing business which Ritholz and the others pursued in North Carolina constituted a violation of the optometry practice act and enjoined them from continuing to do business in that way. Ritholz and the others now seek the court continued, to protect the method of doing business by enjoining any interference with that business by an enforcement of the optometry practice act. But said the court since no effort was being made to enforce the act against them except through the proceedings in the state court, the present action constituted an attempt to enjoin the enforcement of the decree of the state court. A writ of injunction, however,

cannot be granted by any court of the United States to stay proceedings in any court of a state, except cases in which such injunction may be authorized by any law relating to proceedings in bankruptcy. 28 U. S. C. A., sec. 379. Irrespective of the provision in the judicial code just cited the court said, the present suit must be dismissed as an attempt to review by a bill in equity in a federal court the decision of a state court. The issue involved, both in the case decided by the state court and in the case in the federal court, was the right of Ritholz and the others to do business under the methods they were pursuing. This issue was squarely determined against them in the suit in the state court and an injunction was issued accordingly. The rule is well settled that one court of equity will not enjoin proceedings in another court of coordinate jurisdiction. The remedy of the plaintiffs, the court pointed out, if they are aggrieved by the action of the state court, is to appeal to the state supreme court, the action of which in proper cases may be reviewed by the Supreme Court of the United States by writ of certiorari. After litigating the issue in the state court, however, they cannot remove the case to the federal district court, nor can they obtain a review of an adverse decision by filing a bill in equity in the federal district court.

For the reasons stated, the federal district court dismissed the plaintiffs' bill.—*Ritholz et al. v. North Carolina State Board of Examiners in Optometry et al.*, 18 F. Supp. 409.

Medical Practice Acts Violation of Harrison Narcotic Act Involves Moral Turpitude—The medical practice act of Arizona authorizes the board of medical examiners to revoke the license of a physician who is guilty of unprofessional conduct and defines that term to mean, among other things, the conviction of any offense involving moral turpitude. The board revoked Du Vall's license to practice medicine. The superior court of Maricopa County, in a certiorari proceeding affirmed the order of the board, and Du Vall appealed to the Supreme Court of Arizona.

The extent of the power of the court, said the Supreme Court, to review on certiorari is limited to a determination of the question as to whether the inferior tribunal regularly pursued its authority. If the facts stated in the complaint against Du Vall were sufficient to confer jurisdiction on the board to proceed to a hearing, and if a hearing was had at which he was given an opportunity to present his defense, errors and irregularities in the proceedings and in the board's conclusion may not be reviewed on certiorari. While the complaint should state a statutory ground or grounds as cause for revoking a license, it is not necessary that such ground or grounds be set forth with the preciseness and particularity observed in an indictment or information or in a complaint in a civil action. The proceedings before the board are more or less informal. If the accusation is sufficient to advise the physician of the nature and character of the charges so that he may prepare himself to defend thereon, it is sufficient.

The first count of the complaint charged that Du Vall "dispensed, prescribed by prescription or sold drugs for other than medical purposes to a person who was an habitual user of such drugs without any intent or purpose to cure said habitual user of the use of said drugs" and that such conduct was contrary to the ethics and professional conduct of a physician. Du Vall contended that this count was insufficient both in fact and in law, that the statutory definition of "unprofessional conduct" was exclusive and that what he was charged with doing in the count did not fall within such definition. He contended also that if what was charged in the count be admitted as true, it would not constitute unprofessional or unethical conduct because it was not charged that the drugs dispensed prescribed or sold were of the habit-forming kind, such as morphine or cocaine, or that such drugs were destructive to health or character. With this last contention the court agreed and consequently held that the count should be rejected as not being sufficient either in law or in fact. The court deemed it unnecessary to decide whether the statutory definition of "unprofessional conduct" was or was not exclusive.

The second count in the complaint charged that Du Vall had been convicted under an indictment charging him with violating the Harrison Narcotic Act and that the offense for which he was convicted was one involving moral turpitude. The

question here presented, the court said, is Does the conviction of a regular physician under the Harrison Narcotic Act involve moral turpitude? Just what crimes involve moral turpitude is not always easy to say. Generally speaking, crimes that are *malum in se*, which are wrong in themselves, involve moral turpitude, while those that are *malum prohibitum*, acts that are not wrong in themselves but are crimes because prohibited by law, do not. This distinction is not always true. Assault and battery, for instance, is *malum in se* but rarely involves moral turpitude. One of the great evils of the day, the court pointed out, is the consumption of narcotic drugs. Because so many persons become addicts, most of the states, if not all of them, have enacted laws restricting the right to dispense or prescribe such drugs. While the United States cannot control the use of narcotic drugs, it has under the taxing power made the traffic in them more difficult. If there is any one who is to be pitied, the court said, it is the addict of habit-forming drugs of the narcotic kind. He is usually a hopeless loss to society. He is a real menace. He will do most anything to secure the drug to satisfy his cravings and under its influence commit most desperate crimes. No one knows this better than the members of the medical profession, bound by their honor and the Hippocratic Oath to the highest ideals in their relation to society and especially those seeking their advice and help. When one of these has been convicted of violating the Harrison Narcotic Act, the court said, he is guilty of "an act of baseness contrary to the accepted and customary rule of right and duty between man and man." In the present case, the indictment on which Du Vall was tried charged him with making, on the same day, two separate sales to an addict, one for four grains of morphine and the other for three, not in the course of his professional practice and not in pursuance of a written order. How could it be said, the court questioned, that a physician who would do what is charged here is of good moral character, or that he is not prostituting his high profession for material gain?

After referring to several definitions of the term "moral turpitude," the court said that it seemed reasonable that the Arizona legislature, when it provided that a physician's license should be revoked when he was convicted of a crime involving moral turpitude, must have meant as measured by the standards of policy and morality as found in Arizona laws. At the time Du Vall was charged with having violated the Harrison Narcotic Act, the same act under the Arizona law was a felony, punishable by a fine of not less than fifty nor more than one thousand dollars or by confinement in the penitentiary for not more than five years, or both. So we must say that those things which are discountenanced and regarded as evil and accordingly forbidden by society are immoral and that the doing of them contrary to the sentiment of society thus expressed involves moral turpitude and this regardless of the punishment imposed for their doing. *State v. Malins*, 9 N. D. 501, 230 N. W. 735, 71 A. L. R. 190. The proceeding before the medical board to revoke a license is not criminal, the court said, and does not require that every doubt as in a criminal case be resolved in favor of the innocence of the licensee. A conviction under the Harrison Narcotic Act negatives all presumptions of good faith on the part of the defendant and brands him as a person of bad moral character, unfit to practice medicine.

Du Vall finally contended that the order revoking his license was void because it failed to "show the facts essential to the jurisdiction of the board making it." The order of the board omitting formal parts provided

The said Board having fully considered the evidence here to for [sic] submitted and being fully advised in the premises [sic] find [sic] as follows:

That the said respondent Dr. Claude Emerson Du Vall [sic] has been found guilty of unprofessional conduct therefore the Board by unanimous [sic] vote here by [sic] revokes the license of the said respondent Dr. Claude Emerson Du Vall [sic].

In support of his contention Du Vall cited *Blunt v. Shepardson*, 286 Ill. 84, 121 N. E. 263 in which case the entire proceeding was in parol and the order of revocation gave no reason for the revocation. The court very properly held the proceeding void. What was done in that case, however, was very different from the situation here the court said. Du Vall was formally charged with unprofessional conduct of the

charges was incontrovertibly proved. He was given a formal hearing and found guilty of unprofessional conduct. While the order does not state the particular cause for the revocation of his license, reference to the record makes it very clear that it was based on his conviction of a crime involving moral turpitude.

The Supreme Court, therefore, affirmed the judgment of the superior court upholding the revocation of Du Vall's license. *Du Vall v. Board of Medical Examiners of Arizona* (31 Ariz. 66 P. (2d) 1026.

Pharmacists Liability for Mistake in Filling a Prescription—A physician, called to treat the plaintiff for a minor ailment, gave him a written prescription which read: Tablets, hydrargyri chloridi misis comp., Two at bed time as directed," and orally directed that the medicine be taken internally. The prescription was sent to a pharmacy owned by the defendants. The pharmacist, one of the defendants in filling the prescription, dispensed bichloride of mercury tablets in 7½ grains each instead of the compound cathartic tablets called for by the prescription. On each of the tablets dispensed appeared the word "poison" and a skull and cross bone. Attached to the container was the regular label of the pharmacy on which appeared the printed words "for external use only" and the typewritten instructions "two at bed time as directed." The word "poison" in large heavy lettering and a skull and cross-bones were not printed on the label, as was required by law, to designate the poisonous character of the contents of the container. The plaintiff became violently ill after taking two of the tablets. His illness, however, did not prove fatal. He later sued the defendants to recover damages for the suffering and disability which he claimed was the result of their error. From a judgment in favor of the plaintiff for \$350, both parties appealed to the court of appeal of Louisiana, Orleans.

The defendants contended that inasmuch as customarily bichloride of mercury is compounded in tablets and compound cathartic in pills, the pharmacist was justified in filling the prescription as she did because the use of the word "tablet" in the written prescription indicated that the physician intended to prescribe bichloride of mercury. This contention, however, did not meet with the court's approval because, the court said, the words used in the prescription clearly meant compound cathartic and not bichloride of mercury. Even if there was justification for the error, there was extreme negligence in delivering this deadly poison in a container which did not on its face show the dangerous character of the contents as was required by law. The plaintiff was not negligent, as the defendants contended, in failing to notice the small and insignificant warnings on the tablets, consisting of the word "poison" and a skull and cross-bones. Neither was he negligent in failing to notice that the container bore the printed prescription "for external use only," or if he did notice it, in assuming the oral and typewritten instructions of the physician should be followed instead of the printed directions on the container. The typewritten inscription "two at bed time, as directed," said the court, would ordinarily be taken to mean that the medicine should be taken internally.

Although the court was of the opinion that the plaintiff was entitled to a judgment it could not agree with the plaintiff's contention that the judgment was insufficient. The evidence showed that the plaintiff had been suffering with other illness and that much of his disability and pain resulted from them and not from the pharmacist's mistake. The court concluded, therefore, that the judgment for \$350 amply compensated the plaintiff for his sufferings which had resulted from the pharmacist's error.

Accordingly, the court of appeal affirmed the judgment in favor of the plaintiff—*Martinez v. Dejeu et al* (14 La. 2d) 503 So 808.

Artificial Fever in Treatment of Ulcerative Colitis—Ferguson and his associates treated five cases of ulcerative colitis by artificial fever, for the production of which they used the Kettering hypertherm. Their method of treatment consisted of two and one-half to three hours of fever between 104 and 105 F (rectal) three times a week. The number of treatments varied between seven and seventeen, the average being twelve per patient. Each patient responded favorably to fever therapy, the clinical improvement preceded the improvement in the proctoscopic appearance. In most cases, after three or four treatments the number of stools was markedly reduced and bleeding and tenesmus were less. The patients' appetites improved and their weights began to increase. In spite of the clinical improvement, fever treatments were continued until the proctoscopic appearance also had improved, except in one patient, who refused to have more than seven fever treatments. In this patient the appearance of the intestine on proctoscopic examination continued to improve, in spite of the fact that fever treatments were not continued. The use of artificial fever in the treatment of ulcerative colitis is not regarded as a treatment that will produce a permanent cure.

Epidemic of Urban Yellow Fever—Walcott and his colleagues present data from which it seems probable that a small epidemic of yellow fever originated through a person who became infected in the jungle but later remained during almost the entire period of his attack in the town of Cambara, where he infected the *Aedes aegypti* mosquitoes, which in turn caused the outbreak of the urban yellow fever. It is not possible to deny absolutely that the epidemic may have been initiated by some unrecognized case of urban yellow fever in

a person arriving from another city or town, but persistent inquiries failed to disclose acceptable evidence for such a conclusion. The first three cases occurred in close neighbors on the same small premises, and the epidemic developed among persons living in nearby houses who had not been absent from Cambara for three weeks previously. The outbreak subsided promptly following the introduction of adequate measures for the prevention of the propagation of *Aedes aegypti* mosquitoes.

Postoperative Thrombosis and Embolism—Bancroft and his co-workers are confident that the physical factors accepted by most authors (dehydration, stasis, infection and trauma) are the main causes of postoperative thrombosis, thrombophlebitis and embolism. In addition to these factors, it is felt that there must be a biochemical change in the blood which precedes and accompanies thrombophlebitis and embolism, because all the physical factors may be present in certain patients and no accident may occur, while in other patients the minimal number of the physical factors may be present and an accident may result. It is recognized that there are definite bleeding diatheses. If, therefore, it is true that there are potential bleeders, one can readily assume that there are potential clotters. If this theory is true, the authors believed that a careful analysis of the blood factors involved in clotting would reveal a significant change before a thrombus occurs. They describe the tests for blood clotting factors, give the result of their prophylactic therapeutic program and discuss the factors entering into blood clotting, viz., fibrinogen, calcium, prothrombin and thromboplastin. The blood of 920 persons was examined. Of these, 111, or 12 per cent, showed high clotting indexes. Only 46 per cent of the patients having high indexes received prophylactic treatment. No accident occurred in the treated cases. In the untreated group nine accidents occurred. Two of these were unrecognized, as the fibrinogen was the only high factor. Newer preparations of heparin for prophylaxis are much more stable than those previously presented by manufacturing chemists. In the authors' early studies they found that heparin injected intravenously lowered the clotting factors in the blood for only an hour or two and then the blood regained its normal tendency. In the present method of injecting into the muscles about the operative site, the heparin is absorbed much more slowly and therefore must have a longer period of potency. Epinephrine should be added to the mixture so that the possibility of hemorrhage is obviated. In only 1 or 2 per cent of all postoperative cases does thrombosis and embolism develop. The clotting factors are a fairly accurate index of a patient's clotting tendencies and if these patients are observed early and placed on a bleeding diet and given sodium thiosulfate, the morbidity may be definitely reduced.

Etiology of Acute Appendicitis—In the light of the knowledge that the vermiform appendix of man secretes fluid, Wangenstein and his colleagues state that its behavior under conditions of obstruction becomes understandable. Whereas it may have been more readily believed that this segment of the intestinal canal, so intimately related to the colon, should be identified with absorption, the demonstration of its secretory function even though it is slight, lends trustworthy credibility to an obstructive origin of appendicitis. That the vermiform

appendix of man may become easily obstructed is obvious. How this obstruction may come about is not so readily discernible. How the appendix may become totally obstructed in other manners than by foreign bodies and appendicoliths demands explanation. That swelling of the mucous and submucous lymphoid tissue may bring about obstruction of the lumen appears reasonable, that augmentation of the normal physiologic obstruction to emptying by reflex nervous causes may initiate circulatory damage to the appendical mucosa and set in motion the effects of continued luminal obstruction would seem to be not unlikely. Observations suggest that the mechanism for production of fluid by the appendix becomes less efficient with increase in age, when appendicitis is also less commonly observed. A closed loop in which secretion occurs would appear to be particularly hazardous when the luminal capacity is small, as it is in the vermiform appendix. Burget and Dragstedt and their associates have indicated how temporary aspiration of a closed loop, or preliminary washing of it, may permit of its being tolerated with the avoidance of rupture. Undoubtedly the same holds true of the vermiform appendix. With gradual development of obstruction or obliteration, undoubtedly complete luminal obstruction may be withstood without rupture.

Sensitiveness to Light in Certain Dermatoses.—For some time Stokes and Callaway have suspected that intercurrent infections, especially in epidemic waves exercise a sensitizing influence in dermatoses with an underlying allergic or infectious-allergic complex. In the past year in their practice this role has been assumed apparently by an influenzal type of nasorespiratory gastro-intestinal and general infection in the epidemic character of which it is well known that the epidemic prevalence approaches that of the epidemic character of one of eleven outbreaks. It is in the incidence of

dence of pustular relapses and pyogenic dermatoses in the typical dermatologic practice in comparison with that of recurrently epidemic infections of the respiratory and gastro-intestinal tracts that intercurrent infections, in part at least presumably of the virus type, predispose definitely to relapse and presumably to clinically pyogenic and partly pyogenic (acneiform) eruptions. Such relapses show a tendency to occur in persons with familial or hereditary predisposition to pyogenic attacks, occur as mild as well as severe attacks of the intercurrent infection and may even be suspected of occurring in comparatively asymptomatic carriers, surrounded by patients with symptomatically active disease. Their onset tends to follow a period of incubation from seven to eleven days, suggesting the development of an allergic or hypersensitive state, the development of such a state as part of an infectious-allergic complex is still further suggested in certain cases of relapse of primary pyogenic infection by the appearance of sensitiveness to light and apparently also of sensitiveness to both light and drugs.

Fatty Acids and Dermatitis.—Ginsberg and Bernstein made repeated studies of the blood lipids on fifty-six subjects with chronic dermatitis to determine the effect of ingestion of oils (linseed, corn or cod liver) containing unsaturated fatty acids. Their observations give them no reason to believe that there was any characteristic abnormality of the blood lipids in the patients whom they treated or that any specific benefit arises from feeding such patients oils containing highly unsaturated fatty acids. Prolonged administration of unsaturated oils to guinea pigs which had been sensitized to horse serum did not prevent anaphylaxis following injection of horse serum.

- Helium in Obstructive Lesions in Trachea.**—In the treatment of twenty-one patients with obstruction in some part of the pulmonary airway, Kernan and Barach employed the inhalation of a mixture of helium and oxygen. Of these patients, eleven received marked relief from the signs of obstructed dyspnea. In seven of these there was need for tracheotomy, although one of them had tracheotomy as a precautionary measure two days later. All of them recovered. Although the remaining four patients experienced marked relief as a result of the helium and oxygen therapy there was ultimately a fatal outcome, as a result of tumor in two, of a thyroid crisis in one and of bronchopneumonia following recovery and subsequent tracheotomy in one. In three cases little or no relief was evident and in the remaining seven cases partial or temporary relief was obtained, in three cases in which tracheotomy was ultimately performed recovery took place and the other four patients were fatally ill, one with compression due to a mediastinal tumor, one with compression due to aneurysm and two with bronchopneumonia. Observation of the patients who received positive relief in addition to helium and oxygen therapy led to the belief that pressure would have been an additional help in many of the other cases. In some instances helium and oxygen therapy is entirely palliative. When the obstruction is due to pressure of a neoplasm below the site for tracheotomy, the latter is an alternative to treatment with a mixture of helium and oxygen. In one instance the treatment was continued until roentgen therapy accomplished removal of the

constricting force. If prolongation of life is itself justifiable through the use of roentgen therapy, helium and oxygen therapy, in order to sustain life until an attempt may be made to reduce a tumor by x-rays, is indicated. When the pressure is due to an advancing aneurysm, for which there is no medical therapy, it seems pointless to use helium and oxygen therapy and precipitate a situation which would necessitate indefinite treatment. The most favorable field for this treatment appears to be the inflammatory swellings in the air passages that are due to infection or to mechanical irritation. If the patient can be tided over a certain period without suffocation by inhaling helium and oxygen under a slight pressure, the subsidence of the infection or the traumatic inflammation makes complete recovery possible. The authors' intention is not to minimize the importance of tracheotomy but to emphasize that the ability to dispense with tracheotomy by employing helium and oxygen therapy makes less likely the complications following tracheotomy, such as descending infection and bronchopneumonia. In other cases, those in which tracheotomy is indicated, a period of relative relief by the inhalation of helium and oxygen makes the operation less dangerous.

Antitoxic Response to Diphtheric Antigens in Children
—Fraser and Halpern give the results of approximately 600 titrations of serums from 244 children, given three injections of "unmodified" diphtheric toxoid, by showing the percentage distribution of children, by antitoxin levels at certain intervals of

time after the last injection. The antitoxin levels three months after three injections of the unmodified toxoid compare favorably with the levels of antitoxin in a group of "naturally" immune persons. These results were obtained during a time when the incidence of diphtheria infection was low, as evidenced by the morbidity rates, by carrier studies and by the fact that, among the serums serially titrated, in only five instances was there an indication of a rise in antitoxin level due to secondary stimulus.

Barbiturate-Picrotoxin Antagonism—As the work of no previous investigators included a study of oxygen consumption during the period of barbiturate-picrotoxin antagonism, Krantz and his associates studied this phase of the antidotal action. 1 In the white rat picrotoxin significantly antagonizes the depression of oxygen consumption produced by pentobarbital sodium. 2 The increased oxygen consumption produced by epinephrine in normal and in rats depressed with pentobarbital sodium is not effective in antidoting the depressed respiration produced by pentobarbital sodium. Therefore, the antidotal action of picrotoxin against the barbiturates is not primarily an acceleration of oxygen consumption. 3 On the whole rat's brain or on the medullary-pons portion of the rabbit's brain in vitro, picrotoxin fails to combat the depressed potential oxygen uptake, as measured by the rapidity of decolorizing methylene blue solutions. Apparently the antidotal action of picrotoxin is not associated with an increased uptake of oxygen of cerebral tissue in general or cerebral tissue rich in vital centers. 4 Picrotoxin does not apparently stimulate the respiration through the carotid sinus reflex by shifting the acid-base equilibrium of the blood, as the increased respiration occurs without altering significantly the pH of the blood. Therefore the antidotal action of picrotoxin in barbiturate poisoning is attributable mainly to its convulsive action, referred to by Koppanyi and his associates as an "awakening effect."

Renal Excretion of Sulfanilamide—Marshall and his colleagues endeavored to determine the mode of sulfanilamide excretion by the kidney. They studied (1) the clearance of the substance in relation to that of creatinine clearance which presumably measures glomerular filtration, (2) the relation of the plasma concentration of the substance to its clearance and (3) the influence of the rate of the flow of urine on its clearance. In the dog, the sulfanilamide clearance is from 20 to 30 per cent of the simultaneously determined creatinine clearance. If the creatinine clearance is accepted as a measure of the rate of glomerular filtration, from 70 to 80 per cent of the filtered sulfanilamide is reabsorbed in the passage of the glomerular filtrate along the tubule. The sulfanilamide clearance is independent of the plasma concentration of sulfanilamide and is apparently increased by increasing the rate of the flow of urine. Sulfanilamide appears to resemble urea in its excretion in the dog but to be reabsorbed to a greater extent by the tubule. In a few determinations on man, the average sulfanilamide clear-

ance was 22.5 cc per minute. If one considers that the inulin clearance in man averages about 125 cc per minute, it is clear that in man as well as in the dog a large percentage of the filtered sulfanilamide is reabsorbed by the tubule.

Distribution of Sulfanilamide in Organism—Marshall and his co-workers studied the sulfanilamide content of various tissues and fluids of the body, and the relation of the blood concentration to the total sulfanilamide content of the body. Their results indicate that sulfanilamide is almost equally distributed in the tissues of the organism (with exception of bone and fat) and is probably present in equal concentration in all parts of the body if concentrations are expressed per unit of water.

*Asthma Following Prolonged Exposure to Sulfur Dioxide Report of Case H F Dowling Washington—p 299

Asthma Following Exposure to Sulfur Dioxide—The inhalation of sulfur dioxide has two possible implications: the immediate toxic effect and the delayed or chronic effect. Since the gas changes into sulfurous acid on contact with water, it is quite irritating to the respiratory passages, its acrid fumes inciting the coughing which is so familiar to those who have performed blood nonprotein nitrogen tests. Inhalation of concentrations of 0.001 per cent by volume causes extreme discomfort, while 0.1 per cent causes death by paralysis of the respiratory center. Refrigerator repairmen are continually exposed to the inhalation of sulfur dioxide throughout each working day. In the case cited by Dowling there were several indications of the allergic state: (1) the history of asthma in his mother, (2) the occurrence of asthma in the patient as a child, (3) the high percentage of eosinophils in the blood and sputum and (4) improvement occurring at the same time as hyposensitization. The patient had an allergic constitution with no clinical symptoms for the previous seventeen years, and inhalation of sulfur dioxide (during his first few days as a refrigerator repairman) acted as an irritant to the respiratory mucosa, permitting the dust allergen to excite asthma as a symptom complex. The pathologic state of the bronchial mucous membrane in asthma offered a favorable medium for the growth of bacteria and this together with the continued irritating effect of the sulfur dioxide in lowering the resistance of the bronchial tissues accounted for the development of the asthmatic bronchitis.

Use of Ammonium Mandelate in Pyuria—During the last eighteen months, Wheeler has used mandelic acid salts in the treatment of fifty-one patients with acute, chronic or recurrent infection of the urinary tract. Thirty-nine of the patients are free from their urinary infection at present. Infections that are resistant to the action of mandelic acid are fortunately not often encountered in children. If the function of the kidney is good, however, and if there are no severe anomalies, an intensive trial on mandelate therapy may be justified, for some of these infections do clear up under such circumstances. The result of long-standing chronic pyelonephritis in some children if not successfully treated, is a hypertensive state which may terminate in uremia. The knowledge of this not too uncommon end result of chronic infection should encourage one to employ the best methods available to control urinary infections in their initial stages and prevent them from becoming deep seated and chronic. Successful results may be expected in a large proportion of patients if there is good bilateral renal function, if the patient is in the afebrile stage at the time of treatment, if there are no obstructive anomalies of the urinary tract, and if the details of treatment are followed carefully.

Artificial Fever Therapy of Sydenham's Chorea—Kendall and Simpson have subjected five patients suffering from Sydenham's chorea to artificial fever therapy using the Kettering hypertherm. All experienced prompt cessation of choreiform movements. None have had recurrence. There were four females and one male. The duration of chorea prior to administration of artificial fever ranged from ten days to ten weeks in the four severe cases, and in one mild case the chorea had been repeated attacks for one year before artificial fever therapy was given. These patients were given from one to three treatments, the average single fever session being three hours between 104 and 105 F. The period of observation extended

from six weeks to four and one-half years. In addition to the choreiform movements, three patients showed evidence of carditis as demonstrated by mitral murmurs, electrocardiographic changes and tachycardia. The mitral murmurs disappeared in all following treatment. The normal cardiac rate and rhythm was restored. Two patients had polyarticular arthritis, which also responded promptly to artificial fever. No other form of treatment was employed in these cases. All the children tolerated the treatments well, none were injured in any way by the artificial fever treatments.

Tetanus with Total Hemolysis—Hall cites a case of total blood hemolysis, following the intravenous injection of tetanus antitoxin serum, in a young girl exhibiting symptoms of tetanus eleven and one-half days after a firecracker burn which had necessitated administration of prophylactic serum. At the time of hospitalization the girl was found not to be sensitive to the serum, but she was desensitized as a precaution. The explanation is believed to be (1) a hemolysin release through a replaced amboceptor-antiamboceptor combination in the presence of amboceptor sensitization, the serum antilysin acting as the amboceptor, (2) an unusual specific Arthus reaction through red cell fixation of sensitizing hemolysin-antihemolysin elements or (3) a combination of the two.

Diagnosis of Blood Dyscrasias and Allied Diseases—Jeter mentions certain aids in the diagnosis, management and treatment of blood dyscrasias and allied diseases. Routine bone marrow biopsy is probably not indicated but should be made in cases in which other hematologic studies do not lead to satisfactory diagnoses. Neutropenia of various degrees and associated with various conditions are frequently observed. Neutropenia has been found in typhoid, malaria, poisoning from heavy metals, roentgen and radium therapy, pancytopenia of the bone marrow associated with aplastic anemia, and various other conditions. The reticulocyte count by a special vital stain has become necessary in the study of anemias. Syphilis is frequently in the background in occult anemia and, if the diagnosis can be established and antisyphilitic treatment instituted, recovery is more complete than could be expected by symptomatic treatment of the anemia. Acute, subacute and chronic nephritis has been observed to be an obscure cause of obvious anemia. Other chronic diseases such as tuberculosis, diseases of the gastro intestinal tract, particularly amebiasis, polyposis and diverticulitis fall into this group. In simple achlorhydric anemia (so-called chronic microcytic anemia and sometimes called idiopathic hypochromic anemia), if no clue to the etiology can be established and achlorhydria is present along with a normal quantity and quality of leukocytes and thrombocytes, large doses of iron and hydrochloric acid are administered. The results are frequently most spectacular. The diagnosis of hemolytic jaundice, or the so-called congenital familial icterus, is established by chronicity, history of heredity, icterus, splenomegaly, increased fragility of erythrocytes and high reticulocyte count, and recently, as pointed out by Hadcn, the erythrocytes tend to be more spheroid in character than in any other type of anemia. The sickle cell trait which occurs in a certain percentage of normal Negroes is not to be confused with sickle cell anemia. Chlorosis is conspicuous because of the extreme low color index and the characteristic color of the skin. In the author's experience syphilis chemical poisoning roentgen therapy and, occasionally, chronic low grade infections are the causes of aplastic anemia. Too frequently the aplasia of the bone marrow is a terminal condition and elimination of the cause is too late. Hemorrhagic purpura is often, if not always, a syndrome of symptoms with characteristic changes in the blood secondary to some ordinarily obscure primary condition.

Congenital Undescended Cecum—Jordan states that congenitally undescended cecums include at least five varieties.

1 The cecum that has descended as far as the upper part of the right iliac fossa, the ascending colon hangs down vertically, then turns vertically up to the hepatic flexure, thus forming a letter J. 2 The cecum that has descended as far as the front of the right kidney, the ascending colon forms a U, with the right limb shorter than the left. 3 The cecum the descent of which is arrested at some point along the lower border of the liver, the ascending colon forms a U with equal limbs, the hepatic flexure is a little farther to the left than normal. 4 The cecum that instead of moving to the right from its earlier epigastric position descends in the middle line, remaining well forward and free from attachments (hence very mobile) leaving the whole right side of the abdomen to the small intestine. 5 The cecum that remains in its earliest position high in the epigastrium well forward in front of the lower part of the diaphragm. The congenitally undescended cecum causes a high degree of discomfort, while the cecum is heavily loaded thus normal, thus a different from the usual state of affairs in the abdomen. It is the surgeon should realize fully that he is dealing with a case in which the terminal ileum and have no intestinal covering and no mesentery.

Tuberculosis of Cervical Lymphatic Glands—While Reid and Wilkinson recognize that different methods may be employed with excellent results by different workers they outline a method of treatment based on the pathology of tuberculosis of the cervical lymphatic glands that has achieved a measure of success in 119 consecutive cases. The treatment consisted of a combination of constitutional and operative measures, but constitutional treatment has been the fundamental one. In the majority of cases surgical extirpation of the tuberculous glands was a primary measure. The cases were divided into three groups: (1) cases with periaadenitis, (2) cases with adenitis, and (3) cases with adenitis and periaadenitis. In the first group attempts at cure were made by the use of a local disease

is insufficient. Constitutional treatment, therefore, is of paramount importance to prevent progress or recrudescence of the disease. The chief factors in constitutional treatment are rest (restraint from all activity), open air, a liberal balanced diet with an adequate supply of vitamin and heliotherapy. Tonsillar and pharyngeal sepsis in the pathology of tuberculous glands of the neck is of utmost importance. The treatment of a tuberculous abscess arising from a gland depends on whether superadded secondary infection has occurred or not. If there is secondary infection the pus should be evacuated by incision and free drainage should be established. If there is no secondary infection an attempt should be made to treat the abscess by aspiration. The success of aspiration depends on the employment of a technic in which the needle is passed into the cavity of the abscess through and across muscle. The route of the needle is thus closed by the approximation of the muscular fibers. The operation for radical excision of tuberculous glands of the neck is a controversial field in surgery. The main contraindication for the operation is active disease with periaadenitis. The group 1 cases treated by conservative means required on an average 67 months to complete a clinical cure, and twenty-four of twenty-nine gave a good result on discharge. The operative forty-five cases were under general treatment for an average period of 29 months before they passed from this group to group 2 or 3, and were then ready for operation. After operation one month of treatment was given to allow satisfactory healing of the wound. There were good results in all the operative cases. Satisfactory results were obtained in the six cases in group 2 under constitutional treatment. They were retained in the sanatorium for an average period of 32 months. The sixteen cases treated by operation all gave good results and were kept under constitutional treatment for an average period of two months before operation. The statistics of the thirteen cases in group 3 give no useful information, as the group contains such a variety of cases of residual infection that no generalization can be made about them. But the immediate results following treatment in all groups were good except in five cases of group 1. Ten patients did not complete the treatment. It is the authors' opinion that the nasopharyngeal lymphatic tissue is the probable path of entry for the tubercle bacillus in this disease. Tuberculosis of the cervical lymphatic glands is a local disease which does not give rise to metastatic lesions.

"Relapse" Following Sympathectomy—In a series of patients in whom the cervicothoracic ganglion had been removed or its preganglionic fibers divided, Simmons and Sheehan studied the effect of sweating tests, ulnar nerve block and the administration of dilute epinephrine intravenously. The results do not support the explanations of the cause of relapse after sympathectomy offered by Lewis in England and White in America. It has been found that the relapse coincides with the reappearance of vasoconstrictor fibers in the ulnar nerve. It is suggested that regeneration of sympathetic fibers must explain their reappearance.

- *Treatment of Pulmonary Tuberculosis with Gold Salts P Courmont
H Gardere and P Rivollier—p 549
- *Mode of Action of Gold Salts in Pulmonary Tuberculosis P Courmont
and H Gardere—p 559

Treatment of Pulmonary Tuberculosis with Gold Salts—Courmont and his associates point out that the opinions about the efficacy and the method of the treatment of tuberculosis by means of gold salts are contradictory. This is partly due to the fact that the statistics are not comparable as regards the selection of the cases, the type of gold preparation that is employed, the method of treatment and so on. The authors present observations on a material in which these factors were the same. They report about 117 adults from the same clinical department. Only one type of gold salt was used and the preparation was administered intravenously in doses of 0.1 Gm. Among thirty-four patients in whom the treatment was completed, the temperature was reduced in 56 per cent of the cases, the weight was increased in 57 per cent, the sputum was reduced in 50 per cent, the bacilli disappeared in 44 per cent, there was roentgenologic improvement in 25 per cent and the mortality was 23 per cent. On the other hand, in the fifty-four patients who did not receive the gold therapy and in the twenty-nine in whom the treatment was not completed, the corresponding figures were extremely unfavorable and the mortality was twice as high as in the treated group. The favorable action of the treatment cannot be disputed. The authors never observed a severe accident. To be sure, they administered only small doses and strictly adhered to certain rules. In a series of sixty-eight cases they observed twenty-nine with mild and generally early complications, but these accidents by themselves never caused serious consequences. The treatment was at once stopped in the twenty-nine cases as soon as the complications developed. It is of great interest to note that in the patients who developed these early complications the mortality was twice as high as in those in whom the treatment was completed, and the improvements were small in number. As all these cases were in the beginning entirely comparable to those which were submitted to the complete treatment, it may be deduced that the extreme sensitivity to the first injections of the gold preparation indicates that the general resistance of these patients is much lower. From this the authors draw the conclusions that (1) it is inadvisable to continue the gold treatment in these sensitive patients and (2) that the prognosis is quite often unfavorable in the sensitive patients. These points and the loss of weight are the most important ones to be watched in the course of the treatment. The authors remain advocates of the small doses which produce good results and are not followed by grave accidents, the mild reaction which they may elicit makes it possible to determine the sensitivity of the patients.

Mode of Action of Gold Salts in Pulmonary Tuberculosis—Courmont and Gardere show that the study of the mode of action of gold salts in pulmonary tuberculosis is of great importance, because a knowledge of the action mechanism is a guide in conducting the treatment and helps to avoid grave accidents. This action mechanism is complex. Factors that must play a part are (1) the bactericidal power of the gold salts and the increase in the natural bactericidal power of the organism (serum urine), which was proved by experiments, (2) the reticulo endothelial system and the organs, such as liver and spleen, which contain much of this tissue and (3) the focal reactions against the tuberculous lesions. These reactions must remain slight to be useful, if they do not, they provoke complications. The use of small doses (0.05 or 0.1 Gm per week) seems sufficient to induce and sustain the beneficial reaction with the least complications. The pathogenesis of the accidents is likewise extremely complex. They may be due to intoxication (too strong or accumulated doses) with toxic lesions of the liver and kidney, to idiosyncrasy (unforeseen spontaneous sensitivity), or to sensitization acquired by the injections. The mode of action of this sensitization is still being disputed. It is made evident in certain cases by cutaneous tests and by passive sensitization. An important part is played by the general hypersensitivity of the tuberculous organism produced by the tuberculosis itself, which influences all those processes and accidents. The authors conclude that all

these processes are complex and interrelated, that extreme caution is necessary in the use of gold salts, that it is advisable to administer only small doses, and that the treatment should be stopped as soon as complications develop.

in Epileptic Patients Several Cases G Maillard and Mlle Jammet
—p 325

Contraction of Adductors as Sign of Appendicitis—Richet and Netter point out that of all the physical signs of appendicitis the most evident is contraction. According to the cases it is located solely or chiefly in the right iliac fossa, in the lumbo-iliac space, above the crural arch, under the liver, sometimes on the left side, sometimes generalized. Occasionally it is the psoas that is contracted. But whatever may be the severity of the appendicitis there often exists the contraction of the adductors of the right thigh, which is easily made evident. The patient is lying on the back with the mouth open, thighs half flexed, heels flat on the bed and knees touching, the muscular relaxation must be complete. Placing a hand or, better, a finger on the internal edge of each knee, one exerts a pressure directed from within outward, tending to separate the knees one from the other and to press them down with their external surface on the bed, as if one attempted the limitation of the abduction in a beginning coxalgia. It is necessary to use a mild pressure constantly and equally on the two sides. This maneuver is not painful. Exceptionally it is possible to detect an intense contraction of the adductors of the right thigh, the member remaining in an almost vertical plane, while the left knee is easily pressed outward. Nearly always there is a slight contraction, a simple hypertonia, the abduction being less marked on the right than on the left, at the same time there is a sensation of an opposing resistance of the member, which one feels better in repeating the maneuver once or twice, but always with lightness. If the manipulation is made with force, the result is always negative. One of the authors has systematically searched for this sign and has detected it in about 40 per cent of the cases of appendicitis. The hypertonia of the adductors of the right thigh is especially frequent in the acute forms of appendicitis. It is found with equal frequency in adults and in children. The sign has symptomatologic value, because systematic search for it in other disorders on the right side of the abdomen never revealed it. In doubtful cases it has often made it possible for the authors to decide the diagnosis in favor of an appendicitis. In attempting to explain the sign, the authors direct attention to the motor innervation of the adductors.

Anemia in Course of Treatment with Phenobarbital—Having observed anemia in two epileptic patients who had been treated for a long time with phenobarbital, Maillard and Jammet examined the blood of fifteen epileptic patients who had been treated with phenobarbital for several years. In eight of these patients they detected a more or less severe reduction in erythrocytes and also other changes. The authors describe the hemograms of these patients and state that the symptoms of anemia are often latent in these patients so that the existence of the anemia is disclosed only by an examination of the blood. The anemia could be counteracted by reducing the dose of phenobarbital and by treating the patients with liver extract.

Osteitis Fibrosa and Parathyroids in Animal Experiment—Eger shows that by inducing chronic lead intoxication in rats it is possible to elicit changes in the bones that can be compared with osteitis fibrosa in human subjects. The changes in the bones are accompanied regularly by an enlargement of the parathyroids. This enlargement of the parathyroids seems to be a secondary manifestation in a primary disturbance of the metabolism.

Connection Between Pineal Body and Adrenal Cortex—Von Kup gives the clinical history of a boy, aged $3\frac{1}{2}$ years, who exhibited physical, mental and particularly sexual prematurity, which apparently was connected with a hyperfunction of the adrenals or with the endocrine sequels of this hyperfunction. The boy died shortly after the extirpation of a large (830 Gm.) malignant adenoma of the left adrenal cortex. The necropsy revealed changes in the endocrine glands. There was an enlargement of the hypophysis. The pineal body, however, was subnormal in weight. In the pancreas there was hyperplasia of the glandular parenchyma to the detriment of the insular apparatus. The weight of the testes was increased. There was a generalized hypertrichosis. The author shows that the clinical history of the boy corresponds with the pathologic anatomic aspects and permits the following conclusions. There is a close, morphologically demonstrable connection between the function of the adenohypophysis and that of the adrenal cortex. The hyperfunction of the adrenal cortex and the endocrine results of this condition caused an increase of weight of the adenohypophysis. The author has previously pointed out that there is an antagonism between the adrenal cortex and the pineal body and as is well known, between the pineal body and the adenohypophysis. The antagonism between adrenal cortex and pineal body becomes manifest by way of the antagonism between the pineal body and the adenohypophysis that is, hyperfunction of the adrenal cortex causes enlargement (and evidently hyperfunction) of the adenohypophysis, which in turn exerts an inhibiting effect on the development of the pineal body. To the hyperfunction of the adenohypophysis must be ascribed the premature development of the gonads and with this the sexual prematurity. Thus there is also an indirect connection between the adrenal cortex and the gonads. The observations described here are corroborated by cases previously described and by animal experiments.

Bridage for Hallux Valgus H. Schwan—p 1580

Treatment of Gastric Hemorrhages—Meulengracht reports that since 1931 he has treated massive gastric hemorrhages without restriction of diet. His experiences with this method of treatment were made in 368 cases of hematemesis or melena, resulting from acute or chronic ulcers. He found that the hemorrhage was not exacerbated when immediately thereafter the patients were given as much food as they desired. The diet is a purged one and the patients are given five meals daily. In addition they receive alkalis, atropine and iron. The patients are permitted to move in bed as much as they desire. Under the influence of this treatment the subjective condition of the patients is much better than under the former treatment with a gradually increasing ulcer diet. The patients regain their strength rapidly, regeneration of the blood sets in promptly

and the convalescence is shortened. Intake of food into the stomach does not exacerbate the hemorrhage. The mortality from gastric hemorrhage was greatly decreased by this treatment.

Danger of Anesthesia of Injured Male Urethra—Knepper points out that, although in case of an intact mucosa there is no toxic effect from the anesthetic which is introduced previous to cystoscopy, severe or even fatal intoxications have been known to occur in case of an injured mucosa of the urethra or when the mucosa was injured by the pressure of the syringe. It is characteristic for such cases that the signs of intoxication and even death follow rapidly, that is, almost immediately after the toxic substance enters the blood stream. This proves that the intoxication is the result of the direct entrance of the anesthetic into the blood stream, that is, there is practically an intravenous injection of the anesthetic. This is due to the fact that a true submucosa is absent in the mucosa of the urethra and a venous plexus is directly underneath the mucosa. Consequently, any injury that reaches below the mucosa involves an opening of the venous system. The author reports the history of a man, aged 57, who died immediately after anesthesia of the urethra. The necropsy revealed defects in the mucosa near a postgonorrheal urethral stricture and there was evidence that the anesthetic had entered the venous system of the corpus cavernosum. He admits that pressure might play a part in the involuntary injection into the urethral venous plexus, but he thinks that an anesthetic of the consistency of a thin fluid will enter openings into the venous system even in the absence of pressure. For this reason he decided to introduce the anesthetic in the form of a thick fluid. He recommends the following prescription: tragacanth 0.75 to 0.1, glycerin 10, pantocain 0.5 to 0.1, distilled water to 50. Anesthetization is begun ten minutes before cystoscopy and is entirely adequate for the intervention. The viscous character of the anesthetic not only prevents it from entering possible breaches in the urethral mucosa but also facilitates easy passage of the cystoscope.

*Etiology of Menstrual Hemoptysis A. Sattler—p 129

*Occurrence of Weil's Disease in Vienna R. Fleckseder—p 139

Partial Pulmonary Collapse K. Strassler—p 155

Menstrual Hemoptysis—Sattler points out that it is well known that hemorrhages from the lung are especially frequent at the time of menstruation in women with pulmonary tuberculosis. Discussing the causes of the menstrual hemoptysis, the author describes a typical case. Repeated severe hemoptyses at the time of menstruation finally made an intervention necessary, which proved that adhesions which suspended a pulmonary cavity in the pneumothorax space and the enormous hyperemia of the lung and pleura at the time of menstruation were the chief causes of the menstrual hemoptysis. A control thoracoscopy during the intermenstrual period revealed that the severe hyperemia of the lung and pleura had subsided. From this observation the author concludes that a causal connection exists between excessive blood perfusion of the lung and the menstrual process.

Weil's Disease in Vienna—Fleckseder gives detailed histories of three out of six patients with Weil's disease who recently came up for observation in two Viennese hospitals. The first patient was a man aged 42, who frequently fished in the river and who had sustained slight abrasions while doing so. Following this he had Weil's disease with the typical fever curve, severe hepatic impairment, icterus, hemorrhagic diathesis and acute renal disorders with polyuria during the period when the fever subsided. The serum of the patient agglutinated *Spirochaeta icterogenes* with a titer of 1:1000. This case ended in recovery, but the other two had a fatal outcome. Both of the latter patients had been working on canals. In analyzing these cases and in reviewing the literature, the author noted a similarity between Weil's disease and another spirochetal disease, namely recurrent fever, cases of which he had observed during the war. In both disorders the following symptoms may appear: backache, muscular pains, particularly pains in the calves of the legs, severe cerebral symptoms, even delirium, severe conjunctival congestion and iritis, also recurrent periods

of fever, which apparently are connected with the life cycles of the two types of spirochetes. However, there are differences as well as similarities. For instance, in recurrent fever the splenic tumor is more pronounced than in the case in Weil's disease. The behavior of the causal agents differs in that in Weil's disease they are less numerous in the blood and in recurrent fever they are less numerous in the urine. Then there are differences as regards the morphology, serologic reaction and the animal pathogenicity. The author considers the differential diagnosis between Weil's disease and various forms of toxic icterus, pyelephlebitis, cholangitis and so on and discusses the prevention of the disease. He points out that physicians and nurses who take care of patients with Weil's disease, and laboratory workers who handle materials from such patients, must be extremely careful: the latter should wear rubber gloves and eye protectors. In view of the fact that Weil's disease is disseminated by rats, attention should be given to the extermination of rats in canals, slaughter houses, markets and mines. For persons who are especially exposed to infection, such as canal workers, the author recommends protective vaccination with killed spirochetes.

Wiener medizinische Wochenschrift, Vienna

Medicinal Shock Therapy of Schizophrenia. M. Sakel—p. 1108

Cardiac Defects During Childhood.—Hecht discusses the present status of the diagnosis and treatment of cardiac defects in children. He cites two cases in which the cardiac disturbance was of traumatic origin, both being cases of cardiac concussion. He points out that the second case is of especial interest to physicians supervising athletic activities. Further he takes up the various forms of endocarditis, particularly rheumatic endocarditis and the valvular insufficiencies. He says that it is best to begin the treatment of new endocarditis with an energetic medication with salicylic acid, but that good results have been obtained also with aminopyrine. Treatment with digitalis is usually not advisable in endocarditis. In the myocardial defects electrocardiography is often helpful. To be sure, there are cases in which the electrocardiogram remains normal to the fatal end. On the other hand, electrocardiographic changes that develop in the course of diphtheria, scarlet fever and influenza are often reversible. The arrhythmias are discussed. It is pointed out that extrasystoles may occur in the absence of functional impairment. Disturbances in the stimulus conduction system are always a partial manifestation of cardiac defects. Pericarditis presents no unusual features during childhood. The congenital cardiac defect is usually characterized by severe cyanosis. In the latter the treatment is only symptomatic. Following a discussion of the symptoms of cardiac insufficiency, namely dyspnea, hepatic swelling and edemas, the author evaluates strophanthin and digitalis therapy. Then he discusses the use of diuretics and the dietetic therapy of edemas. If hydrothorax, ascites and hydropericardium are accompanied by severe disturbances in compensation they necessitate puncture, severe edemas yield only to capillary drainage. If such severe cases develop during childhood the prognosis as regards life expectancy is much more unfavorable than if it develops in later life.

Heredity of Albinism.—Sanders reports that questionnaires sent to ophthalmologists disclosed 216 cases of albinism in 140 families. Investigations on this material revealed that the heredity of albinism is of the monogenic type. The author directs especial attention to two families in which both the dominant albinism and the recessive albinism were present. He thinks that these are nearly always phenotypically normal.

New Points of View in Research on Cancer.—The Hagedoorns show that in most cases in which hereditary developmental factors influence a disease it is found that a single gene is more or less the determining factor. In cases of cryptorchidism, anemia, deafness and other disorders were found to follow this rule. However, carcinoma of the mammary gland of mice is an exception. In cross breeding experiments between strains with and without cancer, it was found that the female offspring of the females of the group with cancer develop cancer, whereas the female offspring of the males of the same strain do not. From these observations Little and Korteweg draw the conclusion that this is a case of extrachromosomal heredity. However, repeated back crossings with males of the cancer strain finally result in the production of females that do develop mammary cancer, a fact which contradicts the aforementioned conclusion. The authors direct attention to experiments in which it was shown that the animals of the cancer strains do not thrive well, that they are poor mothers and that the young grow poorly. The only way to raise the young to normal, healthy mice was to have them suckled by normal mice. Many of these fostering experiments confirmed the hypothesis that cancer of the breast is induced by the fact that the young mice are suckled by females of the cancer strains. In the females of a cancerous strain which were suckled by their mothers, the incidence of cancer was 83.2 per cent, but in females of the same strain which were suckled by normal animals the incidence of cancer was only 4.9 per cent. Moreover, some young females of strains that were free from cancer later developed cancer when they had been suckled by females of the cancerous strain. The authors suggest experiments that will reveal whether cancer is produced by the presence in the milk of a cancer inducing substance or by the lack of an important substance. They conclude that the so-called hereditary factor in cancer of the breast can be counteracted by a simple intervention during early childhood.

Acetophenetidin Intoxication.—Espersen reviews cases of chronic acetophenetidin intoxication from the literature, discusses the different conceptions of the cause of cyanosis in intoxication with aniline derivatives and reports a case of fatal chronic acetophenetidin poisoning in a woman, aged 39, who for three years had taken 15 Gm. of acetophenetidin daily (in all, between 1,600 and 1,700 Gm.). He says that spectroscopically about three weeks after the last dose of acetophenetidin there was neither methemoglobinemia nor sulfhemoglobinemia. Determination of the oxygen capacity according to Van Slyke and Hiller, about four weeks after the last intake of acetophenetidin, revealed no decrease in active oxygen binding in spite of constant cyanosis, and the arteriovenous oxygen difference was normal. The conception is thus supported that the cyanosis depends on the presence of dark oxygenized para-amino acid combinations. The liver cirrhosis found post mortem is to be interpreted as a result of the long continued acetophenetidin intoxication.

OTOLARYNGOLOGY IN RELATION TO GENERAL MEDICINE

BURT R. SHURLY, M.D.

DETROIT

This subject was selected from deductions forcibly impressed on me during ten years of experience in examinations of more than 2,300 candidates before the American Board of Otolaryngology. That problems of otolaryngology are clearly related to general medicine has been recognized from time to time in the literature and in practice. The earlier otolaryngologists numbered quite a few men who were trained in general medicine first and in otolaryngology later, whereas the modern specialism concentrates the training for a number of years on otolaryngology and to a considerable extent ignores the related and borderline problems.

Postgraduate instruction in this country is an evolutionary training, and the best opportunities are offered in a comparatively few centers. In the effort to stress the highly technical surgical procedures, the allied specialties, such as neurology and internal medicine, are given scanty consideration. The examinations given by the board indicate that the candidates are splendidly prepared in the diagnosis and treatment of sinus disease, pathologic tonsils and adenoids and in the problems of mastoiditis and understand admirably the treatment of diseases of the throat and acute and chronic suppurative conditions in these localities. But the larynx, the thyroid, infections of the respiratory tract and the problems of internal medicine as related to the ear, nose and throat are passed over with lessened interest and limited knowledge. In order that a model curriculum in graduate and postgraduate study may be attained, a plea is made for broader consideration of the borderline problems and their definite relationship.

The patient now comes to the otolaryngologist more and more frequently through his own choice or through the advice of a friend rather than as a referred patient from the general practitioner. Under the newer psychology, the layman selects his specialist himself, in this he is largely influenced by hearsay evidence of the specialist's ability from various channels of indirect advertising. The information that the certified specialist is especially qualified to treat a particular disease is not yet widely disseminated, it will attain popular understanding within the next decade. The choice of the layman may therefore be erroneous in that he makes his own diagnosis and rushes to the specialist he thinks best fitted to care for his trouble.

Many acute infections beginning in the nose and throat and ear may become problems of thoracic disease, infection of the brain, arthritis, syphilis, thyroid disease, pneumonia, tuberculosis, furunculosis, cardiac disease, dyscrasia of the blood or an exanthem, therefore a more extensive knowledge than that supplied by a narrow curriculum is essential. The pendulum has swung so far that the otolaryngologist now limits his knowledge and work to the extent that many serious problems associated with the local conditions are in danger of being overlooked without proper investigation. The economic factor also enters into modern medical investigation, the patient finds himself unable to engage from three to five or more specialists to arrive at a correct interpretation of his condition. It is true that the clinic of a large hospital offers a rotating service of cooperation which will cover the individual problem in many cases. It is equally true that not one of these several specialists has either time or opportunity to become personally familiar with the inner life or personal history of the patient who is usually seen for merely a few minutes of examination and observation.

Many cases of pneumonia or tuberculosis in their incipient stages are passed over by the specialist who has no particular interest in diseases of the chest, which extend beyond his field as organized, limited and approved by the general set-up of specialism.

Under the present regime a physician is popularly sanctioned to be an eye, ear, nose and throat specialist, or an ear, nose and throat specialist and bronchoscopist, with full recognition as such. By the same token a man is not expected to be a certificated neurologist, although the specialties of ophthalmology and neurology are intimately related. Certifying boards are not in favor of issuing more than one or at most two certificates to the same person. The requirements for knowledge in the related specialties must therefore be developed in the postgraduate centers of instruction. How much should an otolaryngologist know about borderline medicine and surgery and of those specialties particularly related to his own? Time and convenience have forced an artificial and arbitrary division of disease within limits that are not founded on pathologic consideration. The eye and ear was a specialty of convenience, quite unrelated, in fact, whereas the specialty of respiratory diseases of the nose, throat and chest has much in common, pathologically, bacteriologically and clinically. The latter had a chair in the medical schools of the Mississippi Valley for many years. Ear, nose and throat offer a logical line of work, which has a reasonable basis of association, but, as disease by extension is so frequent, why should the specialist in this line not be interested and trained also in such problems of internal medicine as are found so frequently

on every candidate for operation on the nose or throat, and the positive reactions have a surprising occurrence in totally unexpected cases. This test, before a submucous operation, is a protection to the patient and the physician, and the same rule holds good for all operative work that does not fall within the realm of emergency operating. While it is true that under the modern system of therapeutics the tertiary lesions of syphilis, as found in the mediastinum, the lymphatic glands and the nervous system, have diminished it is only fair to the patient that any infection of syphilis so readily determined, should not be overlooked. If otolaryngologists are to join in eliminating the ravages of syphilis and in promoting the proper prophylactic measures, Kahn and Wassermann tests must ultimately be made a routine procedure. If the cost of the examination is beyond the financial means of the patient, I believe the department of health should take care of this contagious disease. If this is state medicine, I am for that much of it—to carry preventive medicine into the field of public protection.

It is a simple matter for one who delves in surgery exclusively to become a therapeutic nihilist and scorn the various therapeutic measures that have stood the test of time and practice. The many examinations conducted by the American Board of Otolaryngology show that the importance of pulse, temperature and respiration is too often disregarded. The consideration of the patient as a psychologic unit, as a member of the human family, with the tremendously influential hysterical, psychic, emotional and hereditary factors, may be lost in the study of the case. The anxiety to demonstrate pathologic tonsils sinus infection, acute mastoiditis and the necessity of operation may sometimes cause the otolaryngologist to ignore the underlying peculiarities of the individual patient. This fact is elementary, but in all clinics or hospitals eternal vigilance is necessary to uncover all possible disease at the onset.

Preventive and general medicine with dermatology and otolaryngology, can work together to advantage in this regard. The century-old practice of clinical medicine cannot be separated completely from otolaryngology. The latter evolved from general medicine, separated rapidly under the enormous demands for greater skill in technique, and yet the cycle cannot be completed until the pendulum swings back, as it must in all great movements, to its proper place, and fair consideration is given to all the various scientific facts which influence both the diagnosis and the treatment.

The American Board of Otolaryngology recognizes that the specialty cannot be practiced exclusively but that a 10 to 20 per cent margin for borderline work and related general problems is admissible.

62 West Adams Street

ABSTRACT OF DISCUSSION

DR FRANK R. SPENCER, Boulder, Colo. One hears occasionally of primary laryngeal tuberculosis, the diagnosis having been made without a thorough physical examination and an x-ray examination of the chest. Stubborn diseases of the ears, nose and throat may be much less obscure after a Wassermann test. A biopsy may decide whether a tumor is benign or malignant, and the degree of malignancy according to Broder's classification. The etiology of a paresis or paralysis of the recurrent laryngeal nerve can rarely be determined by the laryngologist. The internist is needed. Fürstenberg's recent article shows the importance of intracranial lesions in the etiology particularly of unilateral laryngeal paralyses and the

help that may be rendered by the neurologist. Recently I saw a patient who lost 18 pounds (8 Kg.) after the successful removal of a malignant tumor. A thorough reexamination and urinalysis showed that he had diabetes. With a proper diet and insulin he has improved rapidly. The malignant tumor was properly diagnosed and removed with an excellent result. The diabetes was not even suspected by the clinical laboratory in an excellent hospital. This will also show that mistakes may be made on either side. In the West we see patients with a diagnosis of pulmonary tuberculosis when the correct diagnosis of bronchiectasis should have been made. This is important because so many patients have sinus disease causing the bronchiectasis. Dr Shurly wants otolaryngologists to think of patients in terms of other organs and other diseases. He wants to see specialists broadly trained. The eagerness with which younger otolaryngologists are seeking graduate courses at the annual meetings of the Academy and their desire to know more about gross and microscopic pathologic changes are very encouraging signs of the times and lead all of us to believe that Dr Shurly will realize his ambition.

DR W. P. WHERRY, Omaha. It is customary to classify medical students as being in the upper middle or lower third of the class and efficiency graphs are drawn by groups. If it were possible to classify practitioners of medicine in the same manner, the errors herein summarized as a graph of the specialty as a whole might fall in the group constituting the lower two thirds. The records now being accumulated by various examining boards will, I am sure, corroborate this assumption. The evaluation of general medicine and of otolaryngology are but a partial yardstick of usable knowledge—the full yardstick is determined by (1) the training background and (2) that innate urge in some to look on this training factor as only an introduction to the threshold of knowledge. In this connection, in the past twelve years it has been my privilege to analyze the results of examination and credential records of 2,400 candidates appearing before the Board of Otolaryngology. I have been impressed with figures showing the groups having the least failure percentage, namely, the three, four and five year residences and the assistant trained divisions. I question whether Dr Shurly, in his analysis of otolaryngologists as a whole has considered the better trained group. Perhaps as the poorer trained sections are eliminated from the scheme of graduate education the graph of otolaryngology (now seemingly dominant) will be redrawn to a higher level. In other words the answer to Dr Shurly's inquiry lies in a consistent program of increasing training facilities, bettering the graduate student output by circumscribing the acceptance into the specialty of those poorly trained.

DR CLAUDE P. BROWN, Philadelphia. One of the difficulties experienced by the clinical pathologists has been due to the physician selecting such examinations as are in agreement with his clinical experience. Nevertheless there is a definite trend to call the clinical pathologist as a consultant and such examinations are made as he considers essential. Bacteriologic examinations supplementing blood examinations certainly are worth while. Normally there may be no bacteria or only a few staphylococci as the nasal secretions are bacteriostatic. When streptococci, pneumococci or *Staphylococcus aureus* are present they are of great clinical importance. Throat cultures of normal patients often show streptococci usually of the viridans type, *Staphylococcus albus* and *Micrococcus catarrhalis*, less frequently pneumococci, hemolytic streptococci and *Staphylococcus aureus*, the latter three frequently pointing to definite infection. As otolaryngology finds itself requiring more training in general medicine so must it also depend on clinical pathology for blood, bacteriologic, serologic and chemical studies and their interpretation. Some otolaryngologists will no doubt be interested in the use of vaccine in ear and sinus infections due to type III pneumococcus. As reported by Dr Goldman, I would suggest that the bacteriologist use broth of from 0.1 to 0.2 per cent instead of 1 per cent dextrose because the acid produced in the latter will kill the pneumococcus before maximum growth occurs also that an eighteen hour period be the time limit. The smears should show mostly gram-positive organisms and, if not, even a shorter period of growth should be used other-

wise maximum immunizing effects will not result from the use of the vaccines. I would make a plea for wider use of vaccines. If vaccines are prepared from organisms such as pneumococci, kept virulent by animal (mouse) passage, no one needs to be much troubled, because the same results will be obtained as if they were prepared directly from the patients' cultures.

DR CHARLES L. BROWN, Philadelphia. I feel that Dr Shurly's paper is most important and especially significant at this time. There have been numerous references throughout the paper and the attendant discussions indicating the importance of adequate special and general training after graduation from the medical school, and also there have been pointed out a lesser number of so-called failures among those men who have been so trained. As Dr Shurly's paper has brought out the comprehensive correlation of internal medicine with otolaryngology, it behooves internists to try to provide the type of training that has been anticipated in the words given by the speakers here. I feel that internists have a difficult problem in doing that. The man seeking qualification in otolaryngology does not wish nor does it seem necessary for him to spend an extensive amount of time in an appointment in internal medicine. Yet in the ordinary hospital organization it is difficult to offer training in internal medicine and nose and throat work at the same time, unless some liaison is established between these two departments. The rotating internship has made this possible in a measure but is unsatisfactory because of the short period of service, it being more adequately accomplished in the two year rotating internship with at least a six months service in medicine. Many of us in institutions are confronted with the problem of providing adequate training for internists as required by the Board of Certification. Since the goal of the majority is the practice of medicine there is merit to a three year plan in which the first year after internship is largely clinical, the second year largely investigative and for special study in the fundamental sciences, allied with medicine, and the third year again largely clinical, the principles learned in the two previous years being applied just before one anchors oneself in practice. Possibly some such arrangement as that might be very valuable in the training of the otolaryngologist, and during this intermediary year a part of the time could be given over to a liaison with the department of internal medicine.

DR EUGENE M. LANDIS, Philadelphia. In the discussion, when a man is oriented in the field of post-nasal disease, it is a common-sense thing to say that a man will be better off if he is trained in the field of internal medicine than if he is trained in the field of otolaryngology. That is, a man who is trained in the field of internal medicine will be better off than a man who is trained in the field of otolaryngology. This is because a man who is trained in the field of internal medicine will be able to handle the problems of internal medicine, which are the problems of the majority of the medical profession. A man who is trained in the field of otolaryngology will be able to handle the problems of otolaryngology, which are the problems of a minority of the medical profession. Therefore, a man who is trained in the field of internal medicine will be better off than a man who is trained in the field of otolaryngology. This is the reason why I feel that Dr Shurly's paper is most important and especially significant at this time.

DR EUGENE M. LANDIS, Philadelphia. This is the reason why I feel that Dr Shurly's paper is most important and especially significant at this time.

OBSERVATIONS ON ACACIA THERAPY IN NEPHROSIS

EUGENE M. LANDIS, MD

PHILADELPHIA

The use of acacia in the symptomatic treatment of nephrotic edema is based on sound physiologic principles, since this particular form of edema is associated directly with massive albuminuria and consequent reduction of the concentration of protein in the circulating blood plasma. The lowered colloid osmotic pressure of the blood disturbs the normal mechanism by which fluid is transported and distributed throughout the body. The resulting massive and persistent anasarca often resists the action of the usual diuretics and renders the chronically nephrotic patient especially subject to streptococcal or pneumococcal infection.

The cause of the hypoproteinemia is not definitely known, it is generally supposed, however, to result from defective formation of protein associated with conspicuous loss of protein in the urine. Theoretically the frequent transfusion of plasma or whole blood is the best form of replacement therapy and is sometimes practicable in treating children. In the treatment of adults, however, when from 20 to 30 Gm of protein is being lost daily in the urine, the protein that can be added in a 500 cc transfusion may be completely excreted within twelve to forty-eight hours. Therefore attention has been directed toward the use of acacia, a colloid which is able to replace temporarily the lacking plasma protein.

Although the intravenous injection of acacia solution had been used for many years as a substitute for blood transfusion in shock or hemorrhage, its application to the treatment of nephrotic edema began with a study by Hartmann and Senn¹ in 1932. Clinical observations have shown that the injection of acacia is not entirely without danger. Austin and McGuinness² reported an alarming increase in blood volume following a single large injection. Maytum and Magath³ raised the question of possible anaphylactic reactions. Undesirable deposition of acacia in the liver has been described by Dick, Warweg and Andersch⁴.

Nevertheless, further studies on acacia therapy in adults seemed desirable owing to the occasionally striking relief of otherwise intractable anasarca. The rapid disappearance of nephrotic edema and subsequently decreased albuminuria and cast excretion led to the suggestion in some clinical reports⁵ that acacia may at times hasten healing of the renal lesion in addition to its purely physical action on the movement of fluid from the tissue spaces to the blood stream. The direct effects of acacia therapy on albuminuria, cylindruria and hematuria in renal disease have so far not been studied in detail. The observations to be reported concern then

selves primarily with Addis counts of the urinary sediment before, during and after the injection of acacia in relatively small repeated doses

Acacia was administered to six patients with nephrotic anasarca and, in far smaller dosage, to two patients with mild glomerulonephritis but no edema. Of the six patients with anasarca, two presented the typical picture of lipid nephrosis without clinical or urinary evidence of glomerulonephritis. One patient had amyloid nephrosis and in three the nephrotic syndrome appeared in the course of early subacute glomerulonephritis with microscopic hematuria, very slightly diminished kidney function, at most a minor and transient nitrogen retention, little or no hypertension, and no cardiac involvement

METHODS

For some days or weeks prior to the institution of acacia therapy, the edematous patients had been on a salt poor, high protein, high caloric diet for the most part under close supervision in a metabolic ward. Fluid intake was restricted and in five instances numerous diuretics had been tried without success. The blood pressure was taken twice daily. Twenty-four hour urine specimens were collected continuously. Fluid intake was kept constant so that, except during diuresis, large changes in specific gravity might be avoided. Albuminuria and chloride excretion were determined daily. By means of the Addis technic the excretion of casts, erythrocytes and leukocytes was estimated at frequent intervals. Urea clearances were determined daily over twenty-four hour periods, as described in a previous paper.⁶ Preliminary skin tests for sensitivity to acacia were negative in all six patients. Commercial 30 per cent acacia was diluted with four parts of distilled water, so that the fluid injected intravenously contained 6 per cent acacia in 0.9 per cent sodium chloride solution. After an initial test dose of from 5 to 10 Gm, subsequent daily doses ranged from 20 to 30 Gm until a total of from 120 to 180 Gm had been given over periods ranging from six to nine days. In agreement with the experience of others, it was found that reactions occurred occasionally unless the undiluted solution as supplied commercially was clear and yellow, or at most light amber, in color. Very slow intravenous injection and the administration of anytal or morphine seemed to assist in avoiding reactions

OBSERVATIONS

The daily injection of from 20 to 30 Gm of acacia (in conjunction with restriction of fluid and salt) produced a satisfactory diuresis and temporary freedom from edema in five of the six cases of nephrotic anasarca. In one case the injection of 140 Gm over a period of six days produced by itself no significant diuresis, but the subsequent administration of theophylline with ethylcynadiminc, U S P (aminophylline) was followed by a copious diuresis, although the latter drug when used prior to acacia therapy had not affected the flow of urine appreciably.

The excretion of chloride in the urine, usually less than 1 Gm in twenty-four hours in patients with nephrotic anasarca, increased temporarily during acacia diuresis to as much as 18 Gm daily. The total amount of chloride excreted during the period of weight loss was roughly equal to the amount of chloride in the

injected acacia solution (4.5 Gm of sodium chloride for each 30 Gm of acacia) plus that of the excreted edema fluid. When diuresis ceased, chloride excretion again returned to its previous low level until dietary salt restriction was made less rigid. The blood pressure was normal, or slightly below normal, in four cases, in two cases, both of subacute glomerulonephritis, the systolic blood pressure was never above 150 mm of mercury. The daily injection of 20 to 30 Gm of acacia did not elevate blood pressure measurably. This contrasts with the effect of a single large dose, which can produce an alarming transient hypertension.²

In none of the six cases was there any clear evidence that the administration of acacia affected hematuria, cylindruria or albuminuria significantly. Chart 1 summarizes observations, characteristic of the group, made during the treatment of a woman, aged 27, with a typical initial attack of lipid nephrosis without clinical evidence of glomerulonephritis. On admission the patient presented massive peripheral edema, pleural effusion and ascites. The body weight ranged from 165 to 170 pounds (75 to 77 Kg), approximately 30 pounds

Chart 1—Effect of acacia on body weight, plasma protein percentage, proteinuria and urinary sediment of a patient with lipid nephrosis

(136 Kg) above her normal weight. The urinary output was less than 200 cc in twenty-four hours. The blood cholesterol was over 600 mg per hundred cubic centimeters and the urine contained doubly refractile lipid bodies. The blood pressure, urea clearance and blood urea nitrogen were normal. As shown to the left in chart 1, the proteinuria ranged from 11 to 27 Gm in twenty-four hours, with a plasma protein concentration of 3.8 Gm per hundred cubic centimeters. Approximately 200,000 casts and 0.7 million red cells were excreted in twenty-four hours.

A diet high in protein and total calories, but low in salt and fluid content, was given continuously throughout the period of hospitalization. During the first thirty days ammonium chloride, thyroid substance and urea in full dosage failed to affect the body weight appreciably. A small area of cellulitis then developed in the right lumbar region. Fear that this infection might spread led to the administration of acacia.

After sensitivity had been excluded, an initial dose of 10 Gm was followed by 20 Gm daily (as shown at bottom of chart 1) until a total of 130 Gm had been injected over a period of seven days. A satisfactory diuresis followed and body weight decreased by 24 pounds (11 Kg) in ten days. Simultaneously, with the onset of diuresis, the plasma protein percentage fell

6 Landis E N, Elom K A, Bott P A and Shiels E H. Observations on Sodium Chloride Restriction and Urea Clearance in Renal Insufficiency. *J Clin Investigation* 14: 225 (Sept) 1935.

rapidly from 40 to 29 Gm per hundred cubic centimeters and then rose slowly after the end of diuresis to reach 41 within thirty days after the injection of acacia was started. Proteinuria, which on admission had been as high as 25 Gm in twenty-four hours, was slightly less than 10 Gm in twenty-four hours on discharge, having decreased slowly and regularly without showing any change that could be referred to acacia therapy (chart 1). The excretion of casts and erythrocytes was not modified in any striking manner during or after acacia therapy. Erythrocyte excretion may have increased slightly and temporarily during the diuresis, but the change was not great and, in any event, did not persist after the diuresis was complete. Blood pressure, blood urea nitrogen and urea clearance (not charted) also showed no significant change during or after acacia therapy.

The effects of acacia were temporary in that fluid reaccumulated unless the plasma protein approached the normal level shortly after diuresis ceased. Thus, as shown in chart 1, the body weight began to increase slowly twenty days after diuresis ended. At this point a blood transfusion was followed by renewed diuresis and the slight residual peripheral edema disappeared. The patient, whose urinary signs persisted, was discharged on a diet high in protein, total calories and vitamins. Edema did not recur, the plasma protein percentage returned to normal and one year later the urine was normal by Addis count and there were no signs of an active renal lesion.

That acacia therapy affects the fluid balance only temporarily is illustrated also by the tendency for edema to return after weeks or months, as the disease again becomes active. One patient, described in full elsewhere,⁸ suffered from subacute glomerulonephritis in the course of which four major attacks of nephrotic

and fourth attacks of edema in this patient were associated with milder grades of hypoproteinemia and were relieved simply by salt restriction and purine diuretics. The renal lesion, in this case a definite glomerulonephritis, remained intermittently active after both injections of acacia. As in the other cases studied, although diuresis was induced there was no evidence from counts that the acacia had affected the underlying renal lesion either beneficially or deleteriously.

It has been known for some time that acacia modifies the properties of the circulating erythrocytes, the surfaces of which are presumably coated by adsorption. The sedimentation rate is increased,⁹ oxygen combining power is modified,¹⁰ and hemolysis becomes more difficult.¹¹ It seemed

possible that adsorption of acacia by renal cells or capillaries might in some way modify the character of the urinary sediment. Therefore, small amounts of acacia were administered to two patients with renal disease but without edema, to study the possible effect on hematuria, albuminuria and cylindruria complicated by diuresis.

Chart 2 summarizes an observation on a patient recovering from acute glomerulonephritis. The blood pressure, originally elevated, had been normal for a period of two weeks before the observations were begun. Tonsillectomy was performed on the ninth day, as shown at the bottom of the chart. Acacia in doses of from 2 to 3 Gm was given daily for eleven days. These injections had no demonstrable effect on the blood pressure, proteinuria, cylindruria, hematuria or leukocyte excretion. So far as could be ascertained, the added colloid passed through the kidneys as an inert foreign body. Similar results were obtained in a patient with active subacute glomerulonephritis, as shown in chart 3. Again the repeated administration of acacia in small doses did not modify blood pressure or the excretion of formed elements in the urine.

COMMENT

Amberson¹¹ has demonstrated the degree to which acacia may take the place of plasma proteins. In dogs it has been possible to reduce the concentration of plasma proteins to 0.05 per cent by repeated plasma pheresis, provided the removed plasma was replaced by 6 per cent acacia in physiologic salt solution. The animals remained in good condition and showed no

most slight edema. In treating nephrotic children, Hartmann and Senn¹ advocated the use of relatively large doses of acacia, namely, from 1 to 2 Gm per kilogram of ideal body weight, repeated if necessary. By calculation this dose should raise the colloid osmotic pressure of the blood to 17 cm of water—the so-called edema level. Austin and McGuinness,² however, observed a dangerous increase in blood volume when this dosage was used in a young adult and suggested that acacia induces diuresis primarily by withdrawing fluid from the edematous tissues and increasing blood volume temporarily. If this is true, diuresis might occur with doses considerably smaller than those advocated by Hartmann.

The observations here reported are in accord with this interpretation in that significant diuresis sometimes began as early as the third or fourth day after only 60 to 80 Gm of acacia had been given. Even if increase in blood volume and loss of acacia from the blood stream are left out of account, this dose would be too small to raise the colloid osmotic pressure of the blood to the "edema level." Rapid decrease of plasma protein concentration and hemoglobin percentage provide additional indirect evidence that blood volume was increased by relatively small doses of acacia.

In these observations acacia was used only in association with rigid salt restriction, which may have increased the effectiveness of the added colloid to some extent. Synergistic action between acacia and the ordinary diuretics seems possible. In one case theophylline with ethylenediamine, U S P, used alone produced no diuresis. Subsequently, after 140 Gm of acacia had been injected without response, the administration of theophylline with ethylenediamine, U S P, in the same dosage was followed by a copious diuresis. It is possible that small doses of acacia, in combination with other diuretics, will prove more reliable and less dangerous than large doses of acacia alone. Definite evidence on this point is, however, still lacking.

The cautious administration of acacia by repeated daily injections of from 20 to 30 Gm appears to be relatively safe and, in combination with salt restriction, has induced diuresis even when the plasma proteins were extremely low. The failure to observe any effect, irritative or curative, on the renal lesion itself agrees with the conclusions of Huffman,¹² who made routine urine studies before and after acacia was administered for hemorrhage and shock in patients without primary renal disease. The colloid is apparently excreted as an inert foreign body even by the diseased kidney, its only effect being the physical one of inducing diuresis when the colloid is present in the blood in sufficient concentration. According to Dick and his associates,⁴ the use of acacia in very large amounts does not raise the blood level in proportion to the dose, because as the concentration of acacia in the blood approaches a certain maximum, which may vary from one person to another, the excess acacia is merely stored in the tissues. Repeated administration of small doses makes it possible to limit the total amount given if diuresis appears early and to discontinue injections if undesirable effects are observed. The danger of suddenly increasing blood volume is avoided and there is time for adaptation. It is probable that, if diuresis has not begun by the time 150 Gm has been given to an adult, little is to be gained by administering larger doses.

In treating nephrotic edema, the usual diuretics should be tried first, since they are in general less apt to produce undesirable side effects. Acacia was given to our six patients for definite indications. In one case it was used because of a threatening skin infection, other diuretics having been tried without success. In the others, rapidly increasing anasarca resisted other therapy and rendered it imperative to induce diuresis promptly or else resort to mechanical drainage or to one of the mercurial diuretics. It is generally agreed that mechanical drainage is hazardous owing to the greater danger of infection in nephrotic patients. Opinion is divided concerning the desirability of using mercurial diuretics in treating a condition characterized by conspicuous tubular degeneration.

The permanent relief of nephrotic edema depends, of course, on the rate at which plasma proteins are formed and the rate at which protein is lost in the urine. According to available evidence persisting improvement after acacia therapy cannot be ascribed to any specific effect of the colloid itself on the renal lesion. Relief of edema does, however, reduce the danger of infection and may favor the development of a spontaneous remission by relieving the anorexia and the gastro-intestinal disturbances that accompany persistent ascites.

SUMMARY

Acacia was administered in repeated daily doses of not more than 30 Gm to six patients with nephrotic edema, the total dosage being 180 Gm or less. In combination with a low fluid intake and rigid salt restriction, acacia produced a satisfactory diuresis in five of the six patients. In one patient acacia per se failed to induce diuresis but apparently increased the effectiveness of theophylline with ethylenediamine, U S P, as a diuretic.

Repeated Addis counts of the urinary sediment before, during and after the administration of acacia did not reveal any definite beneficial or deleterious action of this substance on the underlying renal lesion.

Small daily doses of acacia have so far not produced any change in blood pressure or any dangerous increase in blood volume. Though its diuretic effect is only symptomatic and temporary, acacia has been useful in treating persisting nephrotic edema in patients with marked hypoproteinemias, provided renal insufficiency, hypertension and cardiac failure are not complicating factors.

Before acacia is used, patients should be tested carefully for sensitivity. The total dose should be kept below the level at which marked deposition in tissues occurs. Undoubtedly the ordinary diuretic drugs are preferable if they are efficacious and acacia should be reserved for persistent, severe nephrotic edema that has, by test, resisted other therapy. In such selected cases acacia frequently provides symptomatic relief otherwise unobtainable and also assists in avoiding the dangerous infections to which patients with persisting nephrotic edema are subject.

ABSTRACT OF DISCUSSION

DR. A. R. BARNES, Rochester, Minn. Ever since Hartman in 1933 introduced the use of acacia in cases of edema with hypoproteinemias it has constituted a valuable adjunct to treatment in these cases. Hartman and Landis pointed out that other diuretic measures should be given a thorough trial first. In the original recommendation Hartman suggested the administration of enough acacia to raise the osmotic pressure to about the normal level. According to my experience, such

¹² Huffman, I. D. Solution of Acacia and Sodium Chloride in Hemorrhage and Shock. *J. A. M. A.* 93: 1696 (Nov. 30) 1929.

large doses have not been necessary, because I have found, as Dr Landis has shown here, that when the acacia treatment of this type of edema is successful the response is obtained from smaller doses. Binger and Goudsmith in the last few weeks have studied two cases which raised two interesting questions. These were both cases of lipemic hypoproteinemic edema. Both patients were carefully treated over a sufficient period with the usual diuretic measures, including a high protein diet, salt restriction, administration of salyrgan, administration of large amounts of potassium nitrate and raising the basal metabolic rate, without securing successful diuresis. The patients were then given acacia intravenously in a dose ranging from 15 to 2 Gm per kilogram of body weight. This resulted in a concentration of acacia in the blood of one of these patients of 0.6 Gm per hundred cubic centimeters. Following the administration of acacia in these amounts, a very slight diuresis was obtained. The day following the administration of the acacia, the patients were given salyrgan intravenously, which resulted in very satisfactory diuresis. The fact that satisfactory diuresis is obtained from smaller doses of acacia than those sufficient to bring the osmotic pressure to normal, and the experience that sometimes when one brings up the osmotic pressure satisfactory diuresis depends on the administration of additional diuretics, suggest that there are some factors in the production of diuresis other than the mere raising of osmotic pressure. As Amberson has shown, acacia administered intravenously is the most satisfactory artificial substitute for plasma. According to my experience, if carefully prepared and carefully administered, the drug can be given without untoward results. This presentation teaches us that we may obtain results from much smaller doses. It is a valuable contribution to the treatment of edema associated with hypoproteinemia.

THE PREVENTION AND MODIFICATION OF MEASLES

CHARLES F. McKHANN, M.D.

BOSTON

Sizable decreases have taken place in recent years in the incidence of certain communicable diseases, notably enteric infections, tuberculosis and diphtheria; the incidence of other diseases among them measles has remained unchanged. Public health measures for the control of measles have been entirely inadequate. No satisfactory means of preventing it has been developed, although certain prophylactic measures, such as isolation of children and closing of child day camps, have had a considerable influence on the control of the disease. Nevertheless, the death rate from measles has been a steady decline, as exemplified by the figures for Massachusetts for the years 1920 to 1930 (table 1).

The diminution in deaths from measles may be due in part to the recognition that the disease is particularly dangerous in children of preschool age and that, although almost all persons sooner or later acquire measles, needless exposure, particularly of small children, is unwarranted and should be avoided. Reduction in the death rate may be further attributed to the wider recognition of the desirability of isolating patients with measles one from another. In years past it was customary in hospitals to segregate children with measles in large ward, for group isolation on the basis that they could not transmit the disease to other

coccus and patient B would be a carrier of a streptococcus, and, although it is true that they could not infect each other with measles, they could interchange their usual pharyngeal organisms. In homes, institutions and hospitals where patients with measles have been isolated individually, secondary infections of the respiratory tract have been noticeably less frequent.

The reduction in the incidence of nutritional disorders and deficiency diseases in children, together with improvement in housing conditions as well as extensive progress of child welfare work, has reduced the number of chronically ill, debilitated children, in whom measles found many of its victims.

Long time surveys of disease lead to the conclusion that the severity of certain infections runs in waves dependent in part on the diminished resistance of populations but also on unexplained variations in the virulence of the virus. That fluctuations in mass resistance to measles have been of some importance in the past is shown by descriptions of the severe forms of measles observed in countries and communities from which the disease had long been absent. The theory that it is the current recognition of the dangers of measles, together with improved child health, rather than the uncontrollable factors of cyclic virulence of the virus and of inherited immunity, which has caused the diminution in the death rate is supported to some extent by the change in the types of complications. Involvement of the respiratory tract, otitis media and mastoiditis are less frequent, and noma has become extremely rare. Activation of tuberculosis is less frequently observed, because of the lessened incidence of tuberculous infections, but the incidence of encephalitis, due presumably to the virus of measles itself rather than to a secondary invader, has apparently not been affected.

Attempts to isolate and cultivate the virus of measles have been largely unsuccessful, and dependable prophylactic or therapeutic procedures based on studies of specific etiologic agents have not been forthcoming. Experimental inoculation of human beings may be performed with success and once was used rather extensively.¹ Surprisingly small amounts of blood from patients ill with measles will on subcutaneous injection into normal children induce measles.² I have observed that the disease induced by inoculation differs in no way from the natural disease and does not individually run a lighter course. The attempts of Herrman³ to produce active immunity in infants under five months of age, while they still enjoyed immunity derived passively from the mother, by inoculating them intranasally with secretions from patients acutely ill with measles, represented an interesting step but one which has not been deemed practicable or even entirely safe. When the virus of measles can be successfully cultivated or can even be preserved for long periods to insure its freedom from other organisms or viruses, a trial of the inoculation of patients and subsequent partial immunization with human serum would appear to be justified. Pending the development of better methods of control, passive immunization with human immune bodies of children after they have been exposed to measles would appear to present the most useful procedure in

the prevention or modification of the disease. Yet with complications occurring less frequently, because of better understanding of the dangers of measles, and with the death rate steadily declining, even this procedure need not be used indiscriminately.

Antibodies against measles are found in the blood of almost all patients who have recovered from the disease. The titer of these antibodies is greater in patients recently convalescent but in most persons apparently persists in protective quantities throughout life, possibly, it may be augmented somewhat by repeated exposure to patients with the active disease. The utilization of convalescent serum tried by Weisbecker,⁴ Cenci⁵ and others owes the impetus to its wide use to the reports of Nicolle and Conseil,⁶ Richardson and Connor⁷ and Degkwitz.⁸

Numerous confirmatory studies have established that serum taken from patients recently recovered from measles, administered by intramuscular injections in doses of 4 or 5 cc. to nonimmune exposed persons in the first few days following exposure, results in a temporary immunity in the recipient, preventing the development of measles from this exposure. If the serum is given late in the incubation period, the temporary immunity is inadequate to insure complete protection and a modified form of the disease ensues. In the modified type, the incubation period is often prolonged, this necessitates lengthening the quarantine period for children who have received the serum. The severity of the disease is reduced, the complications and sequelae are minimized and the attenuated attack usually results in permanent immunity. From the standpoint of public health, the desirable use of serum, especially in the case of normal healthy children who have been exposed, would be thus to induce modification of the disease. However, the degree of modification which can be effected and still permit the development of permanent immunity has not been defined. Debre⁹ has maintained that all the symptoms, though in a mild form, must appear if lasting immunity is to result.

When measles breaks out in an institution, hospital, school or convalescent home, modification would not appear to be desirable, rather, the immediate and complete eradication of the disease should be sought, since the attenuated form is still readily communicable and does not eliminate the necessary periods of quarantine. Furthermore, in hospitals many of the patients fall into the groups of acutely or chronically ill, debilitated, or very young children, for whom the fatality rate for measles is highest and who should therefore be protected if possible.

Certain hospitals have for a number of years used convalescent serum effectively in the control of measles. However, even in hospitals the use of convalescent serum has been limited by the lack of adequate supply, control of measles by this means in the general population would be entirely impracticable.

Adult immune serum and adult whole blood have been used as substitutes for convalescent serum¹⁰ on

the basis that adults who have experienced the disease retain antibodies capable of protecting other persons. The dose of adult serum must be much larger than that of convalescent serum (15 cc. of adult serum or 30 cc. of adult whole blood, as opposed to 4 or 5 cc. of convalescent serum). The results are less certain than when convalescent serum is used.

The results with the use of adult serum have led to the general acceptance of the observation that the blood (and possibly the tissues) of most urban adults contains the protective antibodies. Furthermore, if the mothers are immune, infants during the early months of their lives are also immune to measles, apparently by reason of the passage of antibodies from mother to fetus through the placenta. In addition to measles, the new-born infant is usually immune to poliomyelitis, scarlet fever, diphtheria and certain other diseases. The actual presence in the umbilical cord blood of the immune bodies to these diseases has been amply demonstrated.¹¹ These observations have formed the background of the investigations into the use of the human placenta and the blood contained in it as a source of antibodies against measles.

would be figures on a series of persons all known to have been intimately exposed to the disease. They do indicate that fewer failures are to be expected from the use of convalescent serum or placental extract than from the use of adult blood.

The dosage of placental extract as well as that of convalescent serum or adult blood may be influenced by several factors, notably potency, time of administration, age and size of patient and possibly degree of exposure. The only direct method of determining the potency of placental extract has proved to be to test each lot for its ability to prevent measles. The indirect method of using diphtheria antitoxin content as a measure of measles antibodies has been unsatisfactory because the diphtheria antitoxin is apparently segregated almost entirely in the pseudoglobulin fraction of the extract whereas the measles antibody is more generally distributed among the globulins. To base the dose on the nitrogen content of the extract has been a relatively satisfactory method of adjusting dose to potency.

The time of the administration of the antibody is undoubtedly important in determining whether prevention or modification will ensue. Larger doses of immune

In table 3 is shown a more detailed analysis of the results obtained in a study conducted jointly by the Department of Pediatrics, Harvard University Medical School, and the Massachusetts Department of Public Health on the use of immune globulin derived from the placenta in the prevention and modification of

FIGURE 1—Course of infection

globulin in the treatment of measles is based on some extent but the results are not uniform. The appearance of the rash is usually observed in the first ten days after exposure. A moderate dose of 10 cc. of immune globulin given to a patient, together with a small dose of 5 cc. of immune globulin, larger doses of 20 cc. or more may be necessary in some cases of passive immunization. It is important to note that infection occurs much less frequently in children exposed in institutions than in those exposed to a brother or sister in the home. The economic status of the home is also important as exposure in crowded homes is especially intimate and therefore more likely to give rise to infection.

In the acceptance of the above is indicated the proportion of the incubation period in which prevention or modification of the disease may be expected to follow the injection of either convalescent serum or immune globulin. If serum is given in adequate amount during the first five days of the incubation period the child does not usually develop the disease.

measles. The figures for patients intimately exposed are particularly noteworthy, as they represent a rigid test of the efficacy of the material. The separation of the cases into groups according to the effect sought is less accurate, because the beginning of exposure often could not be definitely established. The administration of the placental extract to produce modification of the disease has presented a somewhat difficult problem in the adjustment of doses and the time of administration. Many children received extract either too early or in too large amounts and were completely protected, whereas in a few cases the extract was administered in inadequate amounts or too late, with failure to secure definite modification. Recently, dependable results have been obtained in securing modification by giving extract on the eighth day after exposure in doses ordinarily effective for prevention when given at an earlier date.

Of all children who received the extract without regard for the type of exposure, the proportion protected entirely was 64.3 per cent, a further 30.4 per cent showed modification, and 5.3 per cent showed failure of the extract to produce either protection or modification.

The extract in liquid form has retained its potency for upward of a year. Since the work of Flosdorf and Mudd and of Stokes,¹³ the lyophile process of preservation has been applied to some lots of the extract.

The administration of placental extract intramuscularly has been followed in some instances by local infection.

¹³ Flosdorf, F. W. and Mudd, Stuart J. Immunity 29, 1935. Stokes, Joseph Jr. and McGuinness, A. C. and McGuinness, A. C. Am. J. Dis. Child 50, 255 (Aug.) 1935.

DR CLIFFORD D. SWEET, Oakland, Calif. My experience indicates that measles may generally be prevented if one gets a good convalescent serum and gives it to the child immediately after exposure. When a child is in such a state of health that measles would be dangerous, immune serum should be injected at once. About five years ago I rather enthusiastically injected adult human immune serum for the purpose of modifying measles, injecting it about four days on the average, after known intimate exposure, and obtained a very large number of children who had modified measles, ranging from measles

minute. A polygraphic tracing showed a complete auriculoventricular dissociation. The patient died and necropsy revealed scattered areas of pneumonia. In serial sections there was no lesion of the bundle of His, except a slight increase in fibrous tissue. In the auriculoventricular node there was only slight fatty infiltration. No mention was made of sections through the right and left branches of the bundle of His but such studies are very important, especially when the auriculoventricular node and the bundle of His are entirely or practically normal. Yater, Cornell and Claytor have shown that bilateral lesions of the bundle branches are often the cause of auriculoventricular dissociation. Furthermore the advanced age of this patient, his illness, which was of several months' duration and the slight fibrosis of the bundle without acute changes all suggest that the disturbance in conduction might have been the result of arteriosclerosis. Neuhof's second patient was a man, aged 49 who had lobar pneumonia. One ounce (30 cc.) each of tincture of digitalis and digalen was given prior to the onset of the bradycardia, but no vomiting occurred. The temperature dropped by crisis on the fourteenth day and two days later the pulse rate suddenly fell to between 30 and 44 beats a minute. This rate persisted for a week, during which time the patient was in collapse and semistupor. Nevertheless, the pneumonia continued to resolve. No generalized convulsions occurred but periods of muscular twitchings, deep coma and a barely perceptible pulse were observed. These attacks averaged about one minute in duration. The polygrams were unsatisfactory but it seems highly probable that the patient had a complete heart block. A week after the bradycardia began, the patient suddenly showed marked improvement and his pulse rate was found to have returned to normal. The convalescence continued uneventfully except for a few short periods during which the bradycardia returned

Fig. 1—Electrocardiogram taken two days after the onset of the bradycardia there is complete auriculoventricular dissociation auricular rate 40 and ventricular rate 47

Frommel and Thevenod⁶ reported a case in which there was electrocardiographic evidence of complete auriculoventricular dissociation during pneumonia. The patient was 78 years of age. Following recovery, a two to one block persisted. The authors believed that the block may have been present before the onset of the pneumonia. The age of the patient, the persistence

of the defective conduction and the administration of digitalis during the acute illness all make it very likely that the defect in conduction was the result of previous arteriosclerosis. Von Kiss and Wollek⁷ reported a case in which a boy, aged 4 years, had lobar pneumonia which involved the entire left lung. The fever terminated by crisis on the seventh day. The pulse rate fell to 76

Fig. 2—Diagram of a heart showing the blocks removed for section. Block 1 includes the auriculoventricular node and the first portion of the bundle of His. Block 2 contains the remainder of the bundle of His and the proximal parts of its right and left branches.

and finally to 60 beats per minute and was irregular. The electrocardiogram revealed a PR interval of 0.25 second, there also were dropped beats. The child made a rapid recovery and the electrocardiogram returned to normal. When the patient resumed activity, the partial heart block promptly returned. Rest in bed for five weeks caused the arrhythmia to disappear permanently.

Yater, Cornell and Claytor, and Maham⁸ reviewed the literature on complete heart block with detailed histopathologic studies and found forty-eight acceptable cases. They failed to find a case in which the condition was associated with pneumonia or peritonitis.

It is hoped that the report of the following case may help to arouse interest in disturbances in conduction which are associated with acute infections. Considerable attention has been given to the role of acute rheumatic fever and many articles have been written on diphtheria and a few on influenza. Other causes have been mentioned only occasionally in the literature.

It is rather amazing that in the forty-eight cases previously referred to, there was not a single case of auriculoventricular dissociation, due to acute rheumatic fever that had been studied by serial sections and reported in detail. There was however one case in which the condition was caused by diphtheria and another in which it was caused by tuberculosis. Gross and Fried⁹ studied the bundle of His in sixty cases of rheumatic heart disease, both acute and chronic. Although only one or two sections were examined in each case 60 per cent showed either exudative or vascular changes. When a marked bradycardia or an irregularity of the pulse occurs in an acute infectious disease an electrocardiogram is indicated, for it is only

by this means that an arrhythmia may be proved beyond any doubt. When patients who have defective conduction come to necropsy a thorough investigation of the conduction system should be made by serial sections. A better understanding of the pathologic changes may enable physicians to advance further in the prevention and treatment of this serious complication. In the large majority of cases in which recovery from the primary infection occurs there is a disappearance of the heart block, nevertheless, the presence of complete auriculo-ventricular dissociation, especially when associated with the Stokes-Adams syndrome, may cause a fatal termination in an otherwise nonfatal case.

REPORT OF CASE

A girl, aged 15 years, registered at the clinic March 12, 1937, because of generalized abdominal pain which had been present for two days. March 6, 1937, two days after she had played basket-ball, she had noticed mild soreness across the abdomen, this had persisted one day. March 8 she had had a slight chill and had felt lightheaded. The following day she had left school because of dizziness. These symptoms had persisted and on the day before she came to the clinic she had suffered

other evidence that would cause one to suspect peritonitis or a specific nature, nor was there any history of appendicitis. The prominent signs in the right lower quadrant of the abdomen were the only indications that the appendix was the causative factor. Because of the extensive peritonitis and toxemia, it was decided that conservative measures offered a better prognosis than surgical intervention. The course of the illness was about stationary for four days after admission, the temperature varied between 101 and 103 F and the pulse ranged between 100 and 120 beats per minute. March 16, the fifth day of hospitalization, pain developed at the tip of the right scapula. Roentgenologic examination confirmed the clinical diagnosis of pneumonia, which involved the lower lobe of the right lung. In spite of this complication, the general condition improved slightly. March 18 the third day following the onset of pneumonia and the eighth day of hospitalization, the pulse rate dropped from 104 to 64 beats per minute and remained between 50 and 60 for the duration of the illness. The fall in pulse rate developed gradually over a period of twelve hours.

An electrocardiographic tracing, made two days after the onset of bradycardia, revealed a ventricular rate of 47 and an auricular rate of 40 beats per minute, with complete dissociation (fig 1). Another tracing made two days later did not show any significant change.

March 22, the patient was improving. The temperature had not been as high as 101 F for the past four days and the abdominal pain and tenderness had largely subsided. The pneumonia was resolving satisfactorily but the pulse rate remained about 50 beats per minute. Suddenly at 9:00 p. m. the patient became dyspneic and cyanotic and died within a few minutes.

Necropsy revealed a generalized peritonitis, about 2 liters of slightly purulent fluid was found in the peritoneal cavity. On the coils of intestine there was abundant evidence of fibrinopurulent exudate and the omentum had migrated to the right lower quadrant of the abdomen. The appendix was normal, while in the fallopian tubes there was a mild secondary salpingitis.

In the right pleural cavity there was about 200 cc of yellow turbid fluid, and a thick fibrinopurulent exudate was found between the lower lobe of the lung and the pleura. The lung was essentially normal except for evidence of a resolving pneumonia beneath the pleuritis. The left pleural cavity contained about 100 cc of the same type of yellow turbid fluid but the pleura and lung were normal.

The heart weighed 304 Gm and was reddish brown. The usual amount of epicardial fat was present. There was no evidence of fatty change, fibrosis or degeneration in the myocardium. The four chambers of the heart showed neither hypertrophy nor dilatation. The appendages, the endocardium and the valves were normal. The foramen ovale was anatomically open but functionally closed. There was practically no coronary sclerosis. Cardiac measurements were within normal limits.

The exudate covering the peritoneum consisted almost entirely of fibrin and pus cells. There was no evidence of organization. Many gram-positive diplococci were found. It was necessary to embalm the body before necropsy because only a small abdominal incision was authorized. Nevertheless an attempt was made to take cultures of the peritoneal fluid and exudate in those parts which showed the least evidence of embalmation. The cultures failed to reveal any pneumococci or other organisms.

The exudate covering the right lower lobe of the lung exhibited the typical picture of the exudate of an acute pleuritis with early organization. Many gram-positive diplococci were found. The lower lobe of the right lung showed advanced organization and there were many areas of adult connective tissue. These changes in the lung extended for about 3 cm beneath the pleural exudate. The remainder of the lung contained a few mononuclear cells within many of the alveoli but was otherwise normal. The remaining lobes of the lung were normal. Sections of other organs were practically normal.

Several sections of the myocardium taken at various levels in the septum and ventricles were studied and revealed no

most of this
degeneration

stain of 150

Her past history was unremarkable and her family history did not reveal anything of importance.

The patient was well developed, slightly obese and weighed 100 pounds (45.4 Kg.). The value for the systolic blood pressure was 90 mm. Hg. and for the diastolic pressure was 60 mm. Hg. Her pulse rate was 100 beats per minute. Her respiratory rate was 14 breaths per minute. There was a mild tenderness across the entire abdominal wall but no tenderness in the right lower quadrant. Her roentgen examination of the heart, lungs and thoracic systems was entirely negative.

And a few days before her death a specimen of blood was taken and revealed a specimen of passed blood. The blood was 9 per cent erythrocytes.

It was
peritonitis
story or

normal Sections that were cut after freezing contained no stainable lipoids. Three blocks of tissue were removed for serial sections. One block included the auriculoventricular node and the first portion of the bundle of His and also included about 1 cm of the membranous septum and about 3 cm of the interventricular septum (fig 2). This method required a longer time for fixing than is otherwise necessary and the sections were so large that only after the shrinkage due to fixation could two of them be mounted on a slide. It was necessary that the long axis of the sections be parallel with the long axis of the slide. This technic reduced the tremendous labor required for serial sections of the conduction system. The second block contained the terminal portion of the bundle of His and most of the right and left branches. It was not necessary to study the more distal branches in this case, because of the nature and extent of the lesion found. The third block included the upper part of the sulcus terminalis and contained the sino-auricular node. This block was sectioned parallel to the sino-auricular node while the other blocks were cut in a transverse direction to Tawara's node and the bundle of His. All blocks were fixed and were embedded in paraffin and sections were cut 10 microns thick. In blocks 1 and 2 sections 1 and 2 were mounted on slide 1 sections 31 and 32 were mounted on slide 2 and so on. These were stained with hematoxylin and eosin except for each fifth slide, which was stained with Van Gieson's stain. It should be emphasized however that in hearts suspected of undergoing fibrosis, every other slide or every slide should be stained with Van Gieson's stain or some other connective tissue stain. Each twentieth and twenty first section of block 3 was mounted and stained with hematoxylin and eosin, except for each third slide, which was stained with Van Gieson's stain.

The sino auricular node appeared normal. The usual central artery was seen but neither this artery nor the arterioles were thickened. No changes were observed in the interlacing muscle and connective tissue cells or in the nerves of the node.

The branch of the right coronary artery which passes from the posterior interventricular septum to supply the node appeared normal. Muscle fibers of the auricle connected with the node in the usual fashion.

The auricular muscle near the node showed a slight to moderate degree of granular degeneration with an apparent edema of the cytoplasm. The nuclei appeared normal. The auriculoventricular node was in its usual position on the right of the membranous septum. The size shape number of specialized muscle fibers and their whorl-like arrangements were all normal. The arteries and arterioles showed no abnormalities. The cells of the node however exhibited the same type of change which affected the nearby auricular muscle. The granular degeneration apparent edema and pale staining character of the cells was only slight in the node but became more pronounced as the conduction system was traced toward its termination. After the node merged into the bundle of His the bundle followed its typical course by passing through the membranous septum obliquely and then coming to lie above and to the left of that part of the interventricular septum which joins the membranous septum. In the latter position the left branch began coming off. The bundle revealed the changes already described but to a moderate degree as the left branch passed down beneath the endocardium on the left surface of the interventricular septum, the degeneration became

more marked. Instead of the normal deep red color, the cells were pale pink and were distended by what appeared to be fluid in the cytoplasm (fig 3). Granules within the cytoplasm were marked and no striations could be found. No exudative changes were seen. In the left branch these changes were found in all sections. In addition the myocardium, beneath the bundle of His, exhibited these abnormalities in a small portion which was 2 mm long and which extended about 1 mm beneath the bundle.

The right branch followed its normal anatomic course but it showed even more degeneration than the left branch (fig 4). It was also similar to the left branch in that the lesion was more prominent in the terminal portion. Brown's-Gram stains revealed no bacteria in any portion of the conduction system.

COMMENT

The moderate degree of acute degeneration found in the auriculoventricular node and in the anterior portion of the bundle of His may or may not have produced the complete auriculoventricular dissociation. However, the changes found in the right and left branches were so marked that if the auricular impulses

Fig 4—A normal right branch of bundle of His one may note the normal staining reaction and cellular structure the bundle (Bd) lies beneath the endocardium (End) and is separated from the myocardium (My) by connective tissue (CT). B the degenerated right branch with its pale staining reaction the clear cells are apparently edematous specimens stained with hematoxylin and eosin slightly reduced from a photomicrograph with a magnification of 150 diameters.

had been able to reach as far as these branches, they almost surely could have traveled no farther. The finding of similar areas of degeneration in the auricles and ventricle suggest that the conduction system was involved by an extension of this lesion.

Had the peritonitis and empyema subsided the heart block would, in all likelihood, have disappeared. This is borne out by previous cases of pneumonia and other acute infections. The cellular structure of the conduction system, although degenerated, showed no actual necrosis and probably would have returned to normal.

Signs of peritonitis appeared five days before any evidence of empyema or pneumonia was manifest. However, there was no organization of the peritoneal exudate, whereas that of the pleura was undergoing early organization and the underlying portion of the lung contained young as well as adult connective tissue. It should be recalled that the patient had a chill three days before the onset of abdominal pain.

These observations indicate that the empyema and pneumonia probably preceded the peritonitis but did not become clinically manifest until later.

The gram-positive diplococci found both in the peritonitis and in the pleuritis were probably pneumococci, although this cannot be proved.

There is no clear explanation for the auricular rate of 40. The sino-auricular node was histologically normal. The theory of toxic suppression might be advanced. However, in other cases in which complete heart block is associated with acute infections, the auricular rates are usually normal or rapid.

SUMMARY

In this case a complete heart block developed during the course of peritonitis, pleuritis and pneumonia. The patient died suddenly while recovering from the infection. Necropsy revealed a marked acute peritonitis, acute pleuritis of the right lower lobe and a minimal amount of residual pneumonia. The lesions of the lung and pleura were definitely older than those of the peritoneum. A gram-positive diplococcus was identified in the pleural and peritoneal exudates but cultures were negative. In serial sections of the conduction system there were slight changes in the auriculoventricular node which became more pronounced as the conduction system was followed toward its terminal portions. These changes were in the form of apparent edema and swelling of the cytoplasm and there also was granular degeneration. There was loss of the striations and the cells which were stained paler than normal. The right and left branches of the bundle of His were affected to a marked degree and in some areas the auricular and ventricular muscle exhibited the same type of degeneration.

FURTHER STUDIES WITH THE TUBERCULIN OINTMENT PATCH TEST

ERAST WOLFF, MD

SAMUEL HURWITZ, MD

In previous studies a preliminary test was made to the value of the tuberculin patch test in the diagnosis of tuberculosis. It was found that the use of application of the tuberculin patch test in the high percentage of agreement with the Mantoux test (0.1 mg. of old tuberculin) made this method a most desirable one for general practice. These previous reports deal with a total of some 800 observations. In the present paper we enlarge on our previous results and report our experience with approximately 1,000 new patients.

HISTORICAL REVIEW

In 1907 Moro first described inunction method for the diagnosis of tuberculosis. His ointment consisted of 50 per cent old tuberculin in a base of hydrous wool fat. This, however, proved too insensitive for general use. Nevertheless it stimulated many attempts to improve on the percutaneous method. Hamburger introduced the so-called perkutan ointment which consisted of old tuberculin evaporated to a constant weight

Then followed Moro's diagnostic tuberculin ointment which was made from evaporated tuberculin of old cultures, both human and bovine, in a base of hydrous wool fat. Shortly thereafter Lowenstein prepared "dermotubum" from glycerin broth cultures of human tubercle bacilli evaporated to one twenty fifth volume, filtered and mixed with dead human bacilli equivalent to one-fourth its weight.

Moro developed a concentrated tuberculin ointment containing dead tubercle bacilli and keratolytic substances, which is known as *ektubin*. All the previously mentioned preparations were applied with friction and no adequate control ointment was used. However, Malmberg and Fromm in 1931 devised a tuberculin plaster containing 1 drop of tuberculin per square centimeter and used a control ointment for the first time.

In reviewing the literature on the percutaneous method of tuberculin testing, one is impressed by the fact that comparison in most instances has been made with the Pirquet reaction. The latter method is generally agreed to be definitely inferior to the Mantoux test and has been replaced by it in America at least. Thus to evaluate adequately any new preparation it should be compared to the most sensitive method at present available for the detection of tuberculous infection, which is the Mantoux test. This we propose to do in the ensuing discussion.

PREPARATION OF THE TUBERCULIN OINTMENT

The ointment employed in this and previous studies was prepared in the following manner. Regular tuberculin glycerin broth was inoculated with human culture H-37. The cultures were incubated for four weeks and then sterilized in the Arnold sterilizer. After sterilization the material was evaporated to one fifteenth of the original volume the organisms being left in the material. The evaporated and concentrated material was then triturated to a smooth mixture to which 0.4 per cent phenol was added as preservative. After trituration the material was filled into appropriate tubes. The control material was prepared in exactly the same manner with the exception that the flasks of glycerin broth were not planted with any organisms. The incubation and evaporation were carried out simultaneously with the cultured material.

TECHNIC OF THE TEST

The area usually selected for application of the ointment is the inner surface of the upper arm or the paravertebral region between the eighth and the eleventh thoracic vertebra. The skin is cleansed with benzine or ether and dried. A pea-sized drop of the tuberculin ointment is applied on the right side and a similar sized drop of the control material is placed on the left side. Each of these drops is covered tightly with a 1½ inch square of ordinary adhesive plaster, which is removed in forty-eight hours.

Correlation Between Ointment and Mantoux* Tests in Different Clinical Groups

Classification	Number of Cases	Agreement per Cent	Disagreement per Cent
Negative Mantoux and x ray	573	99.3	0.7
Positive Mantoux, negative x ray	146	93.8	6.2
Positive Mantoux, positive x ray (clinically latent)	210	97.7	2.3
Positive Mantoux, positive x ray (clinically active)	141	100.0	0.0
Total	1060	98.2	1.8

* The Mantoux test was done with 0.1 mg. of old tuberculin. Agreement between the ointment and the Mantoux reaction occurred in 100 out of 100 instances or 98.2 per cent. Discrepancies occurred in nineteen cases or 1.8 per cent.

1. Positive Mantoux, 0.1 mg. negative ointment. This disagreement occurred fourteen times or in 1.3 per cent of total tests. In none of these was there x ray or clinical evidence of activity.

2. Negative Mantoux, 0.1 mg. positive ointment. This disagreement occurred five times or in 0.5 per cent of total tests.

One of the latter patients showed hilar calcification. In four cases the ointment and the intracutaneous test with 1 mg. of old tuberculin were positive whereas the injection of 0.1 mg. of old tuberculin had failed to produce a positive reaction. In one of these cases roentgen examination showed a hilar gland tumor.

Positive reactions are manifested as follows. A weak test shows a few discrete small papules of a pale rose color (fig. 1), a medium reaction consists of many vividly red papules with erythema of the surrounding skin (fig. 2), while a marked positive reaction shows in addition to the preceding condition marked induration and yellowish discoloration of the total test area

Fig. 2—Medium positive reaction. (A) negative control test and (B) ointment patch test.

(fig. 3). Occasionally distinct vesicle formation results. A few papules may rarely be seen under the control type, but only in strongly positive reactors, and no difficulty in interpretation has been experienced.

The color of the positive reaction area begins to fade in about ninety-six hours but may still be discernible after one week. Scaling and brownish pigmentation of the skin may be seen for several weeks after the marked reaction. In contradistinction to the intra-

cutaneous test there has never been a generalized systemic reaction. The only symptom encountered is itching over the positive test area.

CLINICAL MATERIAL AND RESULTS

This paper is based on a study of 1,075 tests done on 964 patients ranging in age from 3 months to 15

Fig. 3—Strong positive reaction. (A) negative control test and (B) ointment patch test.

years. These patients were seen at the children's chest clinic of the University of California Hospital, the outpatient pediatric department of Mount Zion Hospital, and the children's tuberculosis wards of the San Francisco County Hospital. These patients were tested simultaneously with the tuberculin ointment and with 0.1 mg. of old tuberculin by the Mantoux method. The accompanying table shows the correlation between the two methods of testing in the different clinical groups.

The high percentage of agreement between the Mantoux and the tuberculin ointment patch test shows the general sensitivity of the latter method. A striking feature is that in no case of a discrepancy in which the ointment method was negative has there been any clinical or roentgenologic evidence of active tuberculous disease. On the other hand, the ointment test has been positive in every instance of active tuberculosis.

COMMENT

Our results with the ointment described have been better than with any other percutaneous application yet employed. Kundratitz¹⁰ in 270 Mantoux (0.1 mg.) positive hospitalized tuberculous children tested with dermatubulin found discrepancies in favor of the intradermal method in twenty-three cases, or 8.6 per cent. Somewhat better results were reported by Goldberg

10. Kundratitz K. Die perkutane Tuberkulinprobe mittels der Tuberkulin salbe Dermatubulin. Ztschr. f. Tuberk. 42: 222, 1925.

and Gasul,¹¹ who among 109 children observed only two instances in which the Mantoux reaction proved positive while the dermatuberculin test was negative. Hille¹² among ninety-six cases positive to 0.1 mg. of old tuberculin intracutaneously observed only eighty-five positive reactors with Moro's diagnostic tuberculin ointment. Although Malmberg and Fromm¹³ reported a large series of cases controlled by the Pirquet test, only fifty Mantoux positive reactors were recorded and of these forty-nine proved positive to their tuberculin plaster. Verde,¹⁴ comparing the tuberculin plaster test with the Mantoux reaction (1:5,000), found disagreement in seven cases out of 165 children examined in a routine manner; these discrepancies all favored the

overcomes the objection of psychologic shock and pain caused by the use of the hypodermic needle. No positive reactions are encountered as a control test is an integral part of the method and the skin reaction is protected as a routine by the adhesive plaster. The ointment is comparatively easy to prepare, is relatively inexpensive and has been found to retain its potency to a period of at least four years.

SUMMARY

1 The agreement between the ointment patch test and the intracutaneous test with 0.1 mg. of old tuberculin in 1,075 observations was 98.2 per cent. This corresponds closely to figures previously reported to some 800 observations. Discrepancies occurred only in clinically latent cases.

2 The ointment test was positive in every case of active tuberculous disease.

CONCLUSION

The results of a tuberculin patch test with control herein and heretofore detailed warrant the conclusion that in our experience the test may safely be substituted for the Mantoux test with 0.1 mg. of old tuberculin in office and public health practice. We feel that it now merits a thorough clinical trial.

450 Sutter Street—University of California Hospital

MYASTHENIA GRAVIS

REPORT OF A CASE WITH NECROPSY

FRANK E. BARTON, M.D.

AND

CHARLES F. BRANCH, M.D.

BOSTON

We here report the clinical course of an extremely severe case of myasthenia gravis, the effect of treatment on the disease and the postmortem results. The etiology is unknown and although there is some agreement as to the primary microscopic changes in the muscle, each author finds multiple variations in the abnormality of the other organs and each seeks a new theory to explain the disease. Our report is unique in that we shall simply state the facts as we observed them and leave the speculation to others.

REPORT OF CASE

History.—A graduate nurse, aged 27, single, referred to one of us (F. E. B.) with a provisional diagnosis of hyperthyroidism, complained chiefly of loss of weight, nervousness and vocal changes, which began approximately six months prior to admission to the hospital. Increasing fatigue was especially apparent when she walked any considerable distance. It was difficult to swallow or talk, and the face felt stiff. Before the onset of her illness she weighed 180 pounds (82 kg.). She voluntarily reduced her weight without medication to 140 pounds (67 kg.). This was maintained until the present illness. During the six months prior to admission she lost 38 pounds (17 kg.) and became extremely nervous and irritable and had an aversion to food. Ten weeks prior to admission she was confined to bed because of the weakness. The speech became thick and very difficult to understand. Food was regurgitated through the nose and the length of time it took to masticate a meal was progressively increased. She perspired profusely and was intolerant to heat. Such slight exertion as was in bed caused palpitation.

The past history was unimportant except that the patient had followed an illness of several weeks which she described as the grip. While training as a nurse she contracted

From the Massachusetts Memorial Hospital and the First

intra-dermal method. In 1935 Anzen¹⁵ reported on a group of 2,183 patients between the ages of 3 days and 15 years and found an agreement between the tuberculin plaster and the Pirquet test in 98 per cent of cases. Among 1,838 patients in whom a negative plaster reaction was found, 806 were further tested by the Mantoux method and 125 per cent reacted positively. Among fifty cases found to react positively to our ointment patch test, the Mantoux method showed two negative results with the plaster described by Anzen. Further present support of the work with

the ointment patch test. The use of the underlying factor in being attached. It is also quite expensive for wide spread use. Only in this study effort were made to incorporate purified protein derivative powder into an ointment but the results proved very unsatisfactory. As the work progressed with the ointment, it was found because the tuberculin ointment was found to be of a period of four years' duration.

RESULTS OF THE TEST

The ointment patch test which is clinically equivalent to the Mantoux test, its advantages are evident. The ease of application and the fact that it is a general work.

It is a comparison of the results of the two methods.

o metodo

1936

neous and

hull 50

hoarseness and had had periods of fatigability, but as the symptoms were not severe she did not mention them. She had an occasional nonproductive cough. The bowels functioned with difficulty. Menstruation began at the age of 13 years and was always regular and painless.

Physical Examination—The patient was well developed but emaciated and was dyspneic when talking. The voice was hoarse and nasal. The face was flushed and the skin moist. There was marked ptosis of the eyelids, the pupils were dilated and reacted to light and in accommodation. The tongue was slightly coated and dry. The teeth were in good condition. There was decreased excursion of the palate. The face had a masked expression and it was impossible for the patient to whistle. There was no enlargement of the heart, the rhythm was regular and the rate was 112. The lungs were resonant with no abnormal breath sounds. The abdomen showed no masses, spasm or tenderness. There was no edema of the ankles. The fingers showed a fine tremor. It was difficult for her to elevate her legs from the bed and after three attempts it was impossible to do so at all.

X-ray examination of the skull was negative. The chest showed no evidence of substernal thyroid. The heart was small and concave, the left border exhibiting under the fluoroscope the rate of 120 per minute. Examination of the lungs gave negative results. X-ray films of the pharynx and larynx taken with the patient at rest showed deformity of the ventricles with a flattening of the inferior border and concavo-convex superior border. The appearance was practically unchanged during phonation (letter E). Fluoroscopically there were normal deglutitory movements. The oropharynx was not completely obliterated. There was marked limitation of the upward movement of the hyoid bone and larynx. The epiglottis showed incomplete excursion and barium was retained in the epiglottic vallecula and pyriform sinuses. There was no apparent evidence of tumor or inflammatory processes.

A special examination of the eyes revealed pupils 5 mm and reaction normal. Extra-ocular actions were normal. The media were clear. The fundi were normal. The fields were normal by confirmation. Vision was unsteady because of the patient's reduced physical condition. Examination of the larynx revealed no neoplasm. Excursion was definitely less than normal.

Laboratory examinations revealed Basal metabolic rate plus 29 and plus 19. Blood pressure 98 systolic and 54 diastolic. The tuberculin and Schick tests gave negative results. Blood cholesterol was 204 mg. Leukocytes numbered 11,050, neutrophils 76 per cent, lymphocytes 10 per cent, endothelials 11 per cent, eosinophils 3 per cent, hemoglobin 80 per cent and erythrocytes 4,600,000. The blood count did not change materially throughout the hospitalization. Chemical examination of the blood revealed nonprotein nitrogen 35, 40 and 36; blood sugar 100, 95 and 80. Sputum was negative. A complete urinalysis, characteristic of many, showed an alkaline reaction, specific gravity 1.025, total solids 5.8, urea 3.06, albumin slightest possible trace, no sugar, acetone or bile, a rare pus cell, no blood disks, few large epithelials, some phosphatic crystals, no casts. Creatinine nitrogen and creatine nitrogen readings are given in the accompanying table.

Clinical Progress—The patient was admitted to the hospital in a state of shock due to a long automobile ride. Following intravenous injection of saline solution and complete rest she showed slight improvement. Specific medication was not instituted until the ninth day. At this time ephedrine sulfate was given according to the dosage suggested by Boothby.¹ 5 grains (0.5 Gm) dissolved in 8 ounces (240 cc) of saline solution. One drachm (4 cc) of this solution was given from three to five times daily, the doses being distributed before and after meals. One drachm of this solution equals approximately one eighth grain of ephedrine. There was a notable improvement for a time but after a ten day trial it was necessary to suspend this medication because of an increase in the pulse rate, an increase in nervousness and marked incontinence.

Patients with hyperthyroidism often do not tolerate ephedrine well. There is an aggravation of all symptoms, with a good deal of apprehension. It is possible that a patient with myasthenia gravis with an increased metabolic rate will react to the drug in the same manner. During her stay at the hospital one other attempt was made to give ephedrine in a very much smaller dosage, but this brought about the same results. Therefore this type of treatment was discontinued. The fact that ephedrine is not helpful in all cases and appears to be even harmful in some has been reported by Irwin² and Boothby.³

Good nursing, careful feeding and intravenous injection of saline solution led to definite improvement. After two days in which no medication was given other than the regimen just mentioned, aminoacetic acid (glycine or glycocoll) was given as a therapeutic test. The aminoacetic acid was administered as a food, and its effect was supplemented by the use of gelatin. It was given in a daily amount of 30 Gm, divided into six doses. Prior to the use of aminoacetic acid the patient was disturbed by a great deal of thick, tenacious mucus. This symptom abated almost immediately. Mastication and deglutition showed a decided improvement. The patient became interested in her surroundings and enjoyed visitors, and her pulse rate attained a lower level. There was a decided increase of timbre of the voice and the muscles of the lower extremity responded longer to stimuli. There was no vomiting. Because

of the low blood sugar, varying from 100 mg to 80 mg, several intravenous injections of 10 per cent dextrose were given. The injections caused an aggravation of symptoms and a greater degree of fatigue. This observation has been reported by Boothby.³

In the seventh week of her hospital stay the patient was considerably improved. She had passed through two distinct periods of remission and aggravation. She experienced considerable relief from the profuse perspiration that had been so noticeable when she was first admitted to the hospital.

At this time dimethyl-carbamate ester of m-oxypheyl-trimethyl-ammonium-methylsulfate (prostigmin) was administered in the doses suggested by Pritchard⁴ and Laurent.⁵ The first dose was 5 cc subcutaneously with $\frac{1}{100}$ grain (0.00065 Gm) of atropine. This caused considerable muscular twitching, increased intestinal peristalsis and a decided sensation of weakness. The dose was reduced to 2 cc with $\frac{1}{200}$ grain (0.0003 Gm) of atropine three times in twenty-four hours. There was a marked improvement following the use of the drug, this improvement lasting approximately five hours following each injection. Laurent and Walther⁶ believe that the action of eserine and of its analogue prostigmin in the relief of myasthenic symptoms has not yet received a wholly adequate explanation. The suggestion that eserine acts by delaying the destruction of acetylcholine by choline esterase at the motor nerve ending seems the only workable hypothesis at present.

Any substance known to facilitate the production or the utilization of acetylcholine might therefore be expected to exercise a favorable influence on myasthenia."

The patient had improved at this stage to the extent that she sat in a chair for fifteen minutes and had taken three steps at a time. When she was admitted to the hospital she was unable to take consommés, water or fruit juices without great difficulty and considerable choking. At this time she was eating solid food (potato, meat, fruits), was sleeping well and could carry on short conversations with a fairly strong voice. Her temperature was normal and her pulse rate was in the nineties. She was very bright and alert and seemed quite happy. This improvement continued until the end of the ninth week.

Suddenly her pulse became accelerated and of poor quality, there was evidence of cyanosis. She was immediately placed in an oxygen tent. Her respirations became more and more

Fig. 1—Section of the heart showing edema of interstitial tissue, separation of muscle bundles and accumulations of lymphocytes (X 120).

labored, and the cyanosis increased. A tracheotomy was performed and she was returned to the oxygen tent. Prostigmin was given with temporary benefit but the respirations became more shallow and finally she died of respiratory failure.

COMMENT

The similarity between many of the symptoms of hyperthyroidism and myasthenia gravis, particularly with respect to the syndrome of muscular fatigue, has been discussed by Allen⁹ and by Cohen and King.⁸

One of us (F. C. B.) had three similar cases referred with a diagnosis of hyperthyroidism only to have the laboratory and clinical evidence point toward myasthenia gravis. These cases have contributed to the usual treatment of this disease.

The basal metabolism in this particular case remained elevated until death, but the thyroid gland failed to show any microscopic changes. Myasthenia gravis should be considered in the differential diagnosis of hyperthyroidism.

Since the changes found at necropsy in myasthenia gravis were first described by Wills⁹ in 1877, numerous authors have published the postmortem examinations in one or more cases, the most comprehensive reports being those of Starr,¹⁰ Bell¹¹ and Norris.¹² The excellent review of Keschner and Strouse¹³ suggests many possibilities.

For some time the disease was thought to be due to changes in the central nervous system. Attention was then shifted to the myoneural junction and a fatigue syndrome. Some have associated it with dermatitis, others with hyperthyroidism. One author made the novel suggestion that the disease was a "perivascularitis chronica proliferans." The seemingly more than accidental association with thymic tumors is discussed by Bell and Norris, is disconcerted by those cases in which the thymus is normal or atrophic. The disease has been thought to be due to a toxemia by the majority of writers, though just what the source or type of toxin is has not always been clear. A bacterial theory has been expressed but was never substantiated until Butti¹⁴ found streptococoid organisms in the tissue from seven cases. Rosenow and Heilman¹⁵ have produced myasthenia-like lesions in animals by injecting toxin from specific strains of streptococci.

Our case resembles many others reported but presents interestingly divergent features. The myocardium showed as marked a myasthenic reaction or "lymphorhagia" as any of the striated muscle throughout the body. We also noted in all the muscles examined that there were not only evidences of atrophy and Zenker's degeneration of individual bundles but also a distinct inflammatory spectrum. To be sure, this consisted for the most part of the more chronic inflammatory phases with lymphocytic infiltration and fibrosis as well as the characteristic lymphoid accumulation universally described by others, but other features were also present in which the edema and neutrophilic infiltration of acute inflammation predominated, albeit the usual capillary engorgement was not pronounced. A consistent lack of any perivascular or specific vascular lesions was noted except in the pancreas. Here one encountered a patchy acute inflammation of the interstitial tissue with relatively little involvement of the parenchyma. The distinct phlebitis and lymphangitis present at one point would be entirely absent in another group of vessels no more than 2 mm distant.

A severe toxemia was clearly evidenced by the splenitis, the focal necrosis in the liver, adrenals and pancreas, and the mild enteritis. That this was of a peculiar and probably nonbacterial nature is perhaps supported by the fact that the lungs showed very few microscopic changes. Special stains on all the more mentioned tissues and the muscles showed rare gram

positive cocci, certainly having no anatomic relationship to the lesions noted and we seriously doubt that there was any causal relation between the two.

All ductless glands were negative except for the thymus, which was extremely atrophic.

POSTMORTEM EXAMINATION

Unless specifically mentioned, the gross and microscopic appearances of various organs and structures were normal. The necropsy was performed four hours after death. The skin over the entire body was soft, smooth, slightly moist and waxy in appearance. There was a slight conjunctival hemorrhage near the inner canthus of the left eye. No palpable glands were present. The body was not excessively emaciated; the panniculus adiposus was 2 cm deep and the abdominal and mesenteric fat was well preserved. The musculature throughout, including the diaphragm, was markedly thinned; the tissues appearing soft, flabby, friable and a very pale pink.

Heart—This weighed 250 Gm and was not particularly remarkable on gross appearance. There was little subepicardial fat. The myocardium was firm, nonfriable and a pale pinkish brown. The endocardium, valves and coronaries were normal. Microscopically, the myocardium, particularly its outer half, showed marked changes. The muscle bundles showed little evidence of individual degeneration, the cross striations being well defined against a normal staining reaction. There was no cytoplasmic necrosis or vacuolation. The interstitial tissue was markedly edematous and widely separated the muscle bundles. It was infiltrated with large numbers of lymphocytes, occasional endothelials and rare neutrophils. Many areas of 'lymphorrhagia' were present.

Lungs—The right lung weighed 250 Gm, the left 220 Gm. They were not remarkable except for the bronchi, which were slightly reddened and covered with a thick, yellow, tenacious mucopurulent exudate. Microscopically they showed an acute bronchitis and early bronchopneumonia. Interestingly enough, however, there were also a few scattered areas of loosely arranged fibrous thickening of the interalveolar walls, in which were accumulations of lymphocytes. These were more numerous than the customary lymphoid accumulations encountered in the lung and had no resemblance to healed tuberculous foci.

Spleen—The spleen weighed 270 Gm and was firm, smooth, regular and a dark purplish gray. On section the germinal centers were very prominent, standing out sharply as large gray dots 2 mm in diameter against a depressed, moist, dark crimson background which yielded no pulp on scraping. Microscopically the germinal centers were almost completely replaced by masses of infiltrating phagocytic monocytes while the surrounding pulp was heavily infiltrated with neutrophils.

Liver—This weighed 1,470 Gm and was essentially normal.

Gastrointestinal Tract—The stomach showed a total absence of rugae. There was no thickening of the wall; the mucosa was intact. Microscopically there was slight chronic gastritis. The small intestine showed a few scattered patches of mucosal reddening with no evidence of ulceration, induration or serosal involvement. Microscopically it showed an early acute focal enteritis.

Pancreas—This weighed 100 Gm and was distinctly swollen, soft and boggy. Peripancreatic tissue was edematous. Longitudinal section of the pancreas showed no evidence of fat necrosis or hemorrhagic pancreatitis. Milking the tissue brought small heads of yellow, purulent-appearing material to the orifices of the ducts. Microscopically the interstitial tissue showed multiple foci of acute inflammation in which no bacteria could be found. The other interstitial tissue was edematous but showed no general inflammatory infiltration, although minute foci of fat necrosis were present. The acinar and isular tissue showed no inherent abnormality.

Kidneys—The right kidney weighed 120 Gm, the left 130 Gm. They were essentially normal.

Adrenals—Together these weighed 20 Gm. They were normal in gross appearance. Microscopically they showed small areas of focal necrosis in the cortex, being invaded by neutrophils.

Ovaries—These were essentially normal except for a few small follicular cysts of each ovary.

Aorta—This presented very early atheromatous patches throughout.

Organs of the Neck—The thymus weighed 5 Gm. It was extremely atrophic and on section presented a tough, yellow, fibrofatty appearing surface. Microscopically only the faintest scattered remnants of the original tissue remained, including rare lymphoid follicles and corpuscles.

Thyroid—The thyroid weighed approximately 20 Gm and was essentially normal. The parathyroids were essentially normal.

Striated Muscle—Throughout the entire body the striated muscle was soft, flabby, friable and almost colorless, being a very pale pink. Microscopically sections through numerous muscles, including the diaphragm, all showed the characteristic picture theoretically associated with myasthenia gravis. The muscle bundles showed a marked variability in their size, shape and staining reaction. Some fibers were swollen to three times

Fig 2—Section of the thymus under low power showing marked atrophy, slightly reduced from a photomicrograph with a magnification of 25 diameters.

the dimension of others immediately adjacent to them. When so distorted they presented the typical picture of Zenker's degeneration. In the majority of fibers the cross striations were well defined but there was considerable tortuosity and irregularity of individual fibers. All fibers were widely separated by an edematous interstitial tissue heavily infiltrated with large numbers of acute and chronic inflammatory cells. Typical lymphoid accumulations or 'lymphorrhagias' were present as well as extensive general infiltration with lymphocytes and monocytes. Numerous foci of neutrophilic infiltration were present in and about which were lacking any marked capillary engorgement or deposits of fibrin (fig 3). Only the rarest gram-positive coccoid organisms could be found and these seemingly had no relationship to any specific lesion, which gave the distinct impression of being artefactual.

CONCLUSIONS

From an exhaustive study of material at hand it must be concluded that one is dealing here with a case corresponding in general to the pathologic and clinical picture of myasthenia gravis. The reported accounts of the pathogenesis and characteristic changes of the

disease are so variable that one cannot be entirely sure of how accurately one's own observations correspond to the major concepts set forth by others. In this particular case there are no demonstrable pathologic changes of the central nervous system. The thymus is extremely atrophic instead of presenting hyperplasia or tumors as described by many authors. With special stains we have been able to demonstrate coccoid bodies in some of the more severe lesions (pancreas striated muscle), but we cannot demonstrate any immediate causal relationship between them and the pathologic changes observed, and they are not present in sufficient number, so that an artefactual basis might not easily account for them. We have noted, as have one or two authors, that there seems at least in places to be some perivascular involvement, although in our case

Fig. 1. Thymus and degenerating muscle with lymphocytes and neutrophils.

this tended to be a phlebitis rather than an arteritis. The most striking well formed myositis affecting the muscle of the body has been present throughout the course of the heart muscle of locomotion and the trunk of being markedly involved. The slight degree of acute bronchitis is almost certainly an infiltrative terminal phenomenon. This is supported by the presence of large colonies of organisms within the bronchial wall, while the immediately adjacent alveolar tissue shows a very reaction. The scattered lymphoid cells seem to be a lymphoid reaction to pancreatitis and adrenal all have little use.

PROBLEMS PRESENTED BY LESIONS OF THE RIGHT QUADRANT

OTTO C. PICKHARDT, MD
AND
HENRY A. RAFSKY, MD
NEW YORK

The diagnosis and treatment of lesions of the right lower quadrant do not as a rule present difficult clinical problems. But every so often patients with a difficult condition in this region are encountered who not only have run the gamut of diagnostic procedures for years but also have undergone surgical intervention only to have a questionably diseased appendix removed.

In view of the fact that appendicitis is such a comparatively common disease, it is not surprising that the symptoms referable to the right lower quadrant are often ascribed to an inflammatory process of the appendix when in reality the lesion is in the cecum or the terminal part of the ileum. For example it is a well known clinical observation that not infrequently patients with nonspecific granuloma or regional ileitis have an appendectomy performed and subsequently, when the symptoms recur, a pathologic process in the ileum is discovered. Patients with symptoms due to cecal stasis, spasm of the cecum or other lesions in the region are often subjected to the removal of the appendix only to have a recurrence of the clinical syndrome, perhaps in a more persistent form. The cecum may be the site of a benign or malignant tumor or an inflammatory or edematous process, infection, parasitic or allergic in origin, which may give rise to a rather confusing clinical picture.

It is a fact that the usual physical and laboratory examinations do not always reveal the correct diagnosis. Special methods of investigation may be necessary, particularly a study of the small intestine. The diagnostic procedure has not been sufficiently utilized although several observers¹ have stressed its clinical application. We have used it, with modifications, to diagnose lesions of the terminal part of the ileum and the cecum which were not detected by routine gastro-intestinal examinations. In preparing the mixture for this investigation four heaping tablespoonfuls of barium sulfate are emulsified in a quantity of cold water sufficient to fill a 10 ounce glass. Five or 6 ounces of this mixture is given for the oral method while for the duodenal instillation 3 ounces is administered. Films are taken every one or two hours.

In the diagnosis of lesions of the right lower quadrant one must remember that the anatomic relationship of the viscera is such that the symptoms referable to this

area may be due to lesions elsewhere in the body and that, conversely, general abdominal complaints or pain in the lumbar and sacral regions may be due to a pathologic process in the right iliac fossa. Furthermore, it is a fact that lesions of the right lower quadrant are not infrequently associated with other abdominal diseases or systemic infections.

In view of the foregoing facts it was thought of interest to report a series of cases, from both a medical and a surgical standpoint, of lesions of the right lower quadrant which presented various types of clinical problems. Gynecologic cases were not included in this study.

In the accompanying table we have summarized the case reports, emphasizing the use of the measures which were employed to detect and to treat the pathologic processes found. The following protocols are illustrative.

REPORT OF CASES

CASE 1—L. D., a man, aged 41, first seen in June 1935, had a history dating back to 1918 when he had a severe attack of pain in the right lower quadrant with cramps, while on the battlefield in France. He could not pass gas or have a bowel movement. The attack lasted for three days and was diagnosed as acute appendicitis. No operation was done. In 1919 an appendectomy was performed in this country, when after roentgenographic study chronic appendicitis was reported. In 1921 a hemorrhoidectomy and in 1925 an operation for right inguinal hernia were performed. In 1932 the patient had a second severe abdominal attack similar to the one in 1918. Since then he had suffered many similar attacks which increased in severity and were accompanied by frequent mucous stools. The results of numerous routine x-ray and laboratory examinations of all types in many institutions were reported persistently negative. Occult blood was found once in the stool. All observations pointed to spastic colitis and a large ampulla of the rectum.

In February 1936 a thorough roentgenographic study of the gastrointestinal tract gave similar results and in addition pointed to the possibility of some adhesions between the small

Fig. 1 (case 1)—A, four hour film showing that the barium sulfate had stopped short at the ileocecal region. B, a six hour film revealing a lack of proper filling in the lower portion of the cecum. In the upper portion the barium shadow shows quite a sharp cut off at its base. Within the shadow there appear to be coils of terminal ileum.

intestine and the site of the operation for hernia. June 19, 1936 the patient experienced an exceptionally severe attack of pain in the right lower quadrant although he did not report for examination until June 30. He had marked tenesmus and a slight mucous stool every fifteen minutes. Physical examination revealed a point of exquisite tenderness with rigidity midway between the appendix and the hernial scar. Subsequently tenderness was also elicited over the cecum and the ascending colon where a definite doughy mass with borborygmi could be

felt. The temperature and the blood count were normal. The stool showed a large amount of occult blood but no ova. The acute condition gradually subsided, leaving soreness and intermittent cramps which the patient described as a stiffening of the intestine.

A study of the small intestine, oral method, was made on July 2, 1936, and this examination revealed the lesion (fig. 1). The preoperative diagnosis was intussusception of the terminal part of the ileum into the cecum, the probable activating cause

Fig. 2 (case 2)—Characteristic string sign of regional ileitis (Kantor) after duodenal instillation of barium sulfate.

of which was a pedunculated tumor originating at the ileocecal junction. At the operation July 13 chronic intussusception, with a large papilloma of the cecum, was found. The terminal part of the ileum was also constricted. A one stage resection of the terminal part of the ileum, the cecum, the ascending colon and half of the transverse colon was performed with side to side ileocolostomy. The patient made an uneventful recovery, gained 30 pounds (13 Kg.) and is comparatively symptom free.

CASE 6—B. T., a white man aged 63 was well until four months prior to admission, Oct. 22, 1935, when he began to experience attacks of generalized cramplike abdominal pains which bore no relation to food, did not radiate and were accompanied by nausea and constipation. He had lost 16 pounds (7 Kg.) during the preceding four months. Physical examination revealed a slightly distended abdomen with a protuberant umbilicus, the liver was enlarged but the spleen was not palpable. A nonmovable slightly tender mass was felt in the region of the cecum over which there was a tympanic note. The temperature did not go above 100 F. The laboratory examinations revealed a sedimentation rate of 105 mm in forty-five minutes, hemoglobin 92 per cent, red cells 4,500,000, white cells 9,300 and polymorphonuclears 79 per cent (segmented 78 per cent). A roentgenogram of the colon Oct. 25, 1935, revealed a large tumor involving the cecum and the proximal portion of the ascending colon. The descending colon showed numerous large and small diverticula. A diagnosis of malignant growth was made. The surgical division however felt that the condition was inoperable.

The patient was treated medically by means of colonic irrigations, sedatives, antispasmodics and a bland diet. He began to improve and the mass in the cecum gradually disappeared leaving a thickening of the walls. With this clinical improvement there was a gradual decrease in the sedimentation rate to 6 mm in forty-five minutes. Another roentgenogram of the colon taken Nov. 4, 1935, failed to show any evidence of the

Summary of Case Reports

Case	Diagnosis	Comment	Case	Diagnosis	Comment
1 L D	Intussusception of ileum into the cecum with papilloma of cecum	Illustrates value of special x-ray studies of intestine as attack is subsiding but before it has entirely disappeared (fig 1) Described in detail	Case 9—Continued		
2 L M	Regional ileitis	Illustrates the fact that by means of a special study of the small intestine a lesion can sometimes be definitely diagnosed the patient a woman aged 22 had an appendectomy performed for attacks of pain in right lower quadrant of 4 months duration her symptoms recurred once and a half months after operation routine x-ray studies gave negative results a study of the small intestine (duodenal method) definitely revealed the lesion (fig 2) resection was performed	10 A F	Perforation by foreign body of cecum with extensive hyperplasia of adjacent lymph nodes	Illustrates the diagnostic problem presented by perforations of the cecum and the surgical procedure necessary described in detail
3 E F	Diverticula of cecum and probable polyposis of terminal portion of ileum	In a patient with periodic attacks of pain in right lower quadrant diagnosed as chronic appendicitis a study of the small intestine (oral method) revealed diverticula of the cecum and small filling defects in the terminal portion of the ileum which owing to their circular shape suggested a polypoid membrane routine gastrointestinal roentgenograms did not show the lesions (fig 3)	11 M O C	Postoperative adhesions around cecum and calculous cholecystitis	Illustrates the advantage of a thorough examination to reveal abdominal diseases coexisting with a lesion in the right lower quadrant (fig 6) described in detail
4 L	Adenocarcinoma of colon at ileocecal junction	Illustrates the fact that in a case of periodic attacks of abdominal pain and constipation a roentgenogram of the colon may not show any morphologic defect a study of the small intestine (duodenal method) revealed typical step ladder levels and marked dilatation of the coils of the small intestine this pointed definitely to the presence of obstruction which was diagnosed as due to malignant process operation revealed an adenocarcinoma at ileocecal junction which was removed in one stage (fig 4)	12 E S	Angioneurotic edema with visceral manifestations	Illustrates the diagnostic value of history eosinophilia in a patient with angioneurotic edema the onset of the attack resembling appendicitis described in detail
5 C D	Adenocarcinoma of cecum	Illustrates the fact that malignant process in the cecum may resemble acute appendicitis in a woman aged 35 complained of periodic attacks of cramps in right lower quadrant for two years the attacks increased in severity the last one being accompanied by nausea and vomiting a hard tender fist-sized mass could be felt in right lower quadrant temperature 101 F white blood cells 17,300 polymorphonuclears 80 per cent a diagnosis of abscess in appendix was made in the course of further questioning patient stated that at times she passed a considerable amount of bright red blood after colonic irrigations this she attributed to hemorrhoids which were treated after further questioning and physical examination a diagnosis of carcinoma of cecum was made operation revealed an advanced adenocarcinoma of cecum anterior portion of cecum was so thin that only the cecum protected it from perforation one stage resection with ileocolostomy was performed patient made an uneventful recovery	13 M S	Gastrointestinal allergy with symptoms resembling appendicitis	Illustrates the fact that at times gastrointestinal allergy may produce attacks resembling appendicitis scratch tests revealed the allergens described in detail
6 B T	Diverticulitis of cecum	Illustrates the fact that an inflammatory process of the cecum may simulate malignant growth and also illustrates the diagnostic and prognostic value of the sedimentation rate of the blood described in detail	14 D S	Spasm of cecum due to a nutritional disturbance	In a patient on whom an appendectomy had been performed followed by a recurrence of the symptoms the finding of hypochlosterolemia indicated the presence of an underlying nutritional disturbance described in detail
7 R F	Acute intraperitoneal abscess probably appendiceal in origin	Illustrates the value of thorough physical examination and the fact that in the presence of an acute inflammatory process x-ray appearances may be misleading described in detail	15 A R	Spasm of cecum of undetermined origin	A roentgenogram with double contrast medium after atropinization revealed a normal cecum although a diagnosis of malignant disease had been made by routine examination patient has been symptom free since first observed two years ago
8 F R	Acute gangrenous appendicitis and cholecholelithiasis	Illustrates the fact that irreversibility of previous operative observations and typical history the patient with an acute condition in the abdomen should be most carefully examined for the possibility of acute appendicitis	16 S O	Primary tuberculous retroperitoneal adenitis	Illustrates the fact that primary tuberculous adenitis must be considered when a small mass is palpable in right lower quadrant even though evidence of tuberculous cannot be found elsewhere in the body the history and physical appearance point to appendicitis a large tuberculous node and the appendix were removed subsequent treatment of the patient at the E. A. Institute and similar treatment in the country helped to restore her health and well being
9 L	Intussusception of ileum into the cecum with papilloma of cecum	Illustrates the value of special x-ray studies of intestine as attack is subsiding but before it has entirely disappeared (fig 1) Described in detail	17 M G	Tuberculosis of cecum and pulmonary tuberculosis	The lesion in the right lower quadrant was secondary to a focus in the lung although patient had been treated for cold a thorough examination revealed pulmonary tuberculosis with positive sputum secondary tuberculosis of cecum was diagnosed by observation of tubercle bacilli in feces and by x-ray study
10 A F	Perforation by foreign body of cecum with extensive hyperplasia of adjacent lymph nodes	Illustrates the diagnostic problem presented by perforations of the cecum and the surgical procedure necessary described in detail	18 B R	Mucocoele of appendix	In patients with history typical x-ray evidence pointing to a malignant process in the cecum the presence of a movable tumor should make one think of the possibility of a mucocoele of the appendix
11 M O C	Postoperative adhesions around cecum and calculous cholecystitis	Illustrates the advantage of a thorough examination to reveal abdominal diseases coexisting with a lesion in the right lower quadrant (fig 6) described in detail	19 J D	Inflammation of retrocecal appendix	While the history and presence of red blood cells in the urine indicated lithiasis of the urinary tract careful examination determined the presence of an inflamed retrocecal appendix
12 E S	Angioneurotic edema with visceral manifestations	Illustrates the diagnostic value of history eosinophilia in a patient with angioneurotic edema the onset of the attack resembling appendicitis described in detail	20 W W	Regional ileitis with abscess formation and peritonitis	Illustrates how varied a clinical picture a case of regional ileitis may present first a case of regional ileitis was treated for three years at one time it was the patient had a pimple ulcer and it started for it gave him relief for one year then it started again simulated a phlebotomy the fact that appendicitis was the cause of the disease in case of ileitis at the only place of drainage of the abscess was the ileocolostomy was at the only place of drainage

previous tumor formation in the cecum but did reveal diverticula in the cecum, transverse colon and descending colon

The patient made an uneventful recovery and left the hospital symptom free, with a diagnosis of diverticulitis, which probably was the underlying inflammatory process. What additional pathologic change caused the roentgenographic defect and the

pain, the first and the second being accompanied by jaundice Feb 15, 1937, the patient had another attack which at first was thought to be due to biliary calculi as the others probably were. She did not improve. The next day she was brought to the hospital. Physical examination revealed marked distention of the abdomen, general peritoneal rebound signs and exquisite tenderness in the right lower quadrant. A tentative diagnosis of appendicitis was made and immediate operation was advised. Acute gangrenous appendicitis with a walled abscess, was found.

CASE 10—A F, a white girl aged 5, was referred to the hospital as having acute appendicitis on Feb 20 1923. Her chief complaints were pain in the lower part of the abdomen, occasional vomiting and fever of four days duration. Examination showed an obliquely placed, elongated firm tender and nonmovable mass in the right lower quadrant. The blood count showed white cells, 35 000 and polymorphonuclears 89 per cent. During the next ten days the temperature and the pulse rate receded almost to normal. The bowels now moved regularly, but the mass remained unchanged. Roentgenograms showed outside pressure against the cecum and the ascending colon.

A tentative diagnosis of retroperitoneal lymphosarcoma was made and an operation performed on March 5. The tumor consisted of a large mass of lymph nodes between folds of mesentery extending from the hepatic flexure to 6 inches beyond the ileocecal valve. Side to side ileocolostomy into the mid-portion of the transverse colon was performed. The lymph nodes removed at operation showed simple hyperplasia and edema with no evidence of tuberculosis or malignancy.

A second operation was performed two weeks later. The mass had decreased materially in size and the site of the ileocolostomy had healed perfectly. At this time the mass and the involved portion of intestine were removed. Pathologic examination of the intestine and the tumor mass revealed acute suppurative colitis with a perforation 2 cm above the ileocecal valve, and lymphadenitis. The tract of the perforation was lined with granulation tissue and covered in places with cylindric epithelium derived from the mucosa of the intestine. In places minute abscesses were present and giant cells of the foreign

Fig 3 (case 3)—A diverticula of the cecum. B small filling defects in the terminal portion of the ileum which owing to their circular shape suggested a polypoid membrane. The appendix was also visualized.

mass, both of which subsequently disappeared is problematic. We do know, however, that at times diverticulitis elsewhere in the colon may resemble a malignant disease. The patient was readmitted to the hospital Oct 19 1936 for a transurethral resection of the prostate gland which was successfully accomplished.

CASE 7—R F, a white man aged 64 complained of pain and a lump in the right lower quadrant of one week's duration which, after x-ray examination of the gastro-intestinal tract was diagnosed as an inoperable malignant condition of the cecum. The previous history was irrelevant except for a gastro-enterostomy ten years before for an ulcer of the stomach. On physical examination the patient was acutely ill with generalized abdominal tenderness, moderate distention and an exquisitely tender mass in the right lower quadrant which was not movable and did not cross the midline. Rectal examination revealed tenderness and bulging in the right fornix. When the examining finger was removed gas was passed. The temperature was 101.8 F and there were 13 400 white cells, with 80 per cent polymorphonuclears. The diagnosis was intraperitoneal abscess probably appendiceal in origin. The operation showed a large abscess with foul pus having a colon odor and with a thick edematous wall. The pathologic report was 'chronic suppurative granulation tissue with no evidence of tuberculosis, syphilis or malignant change.' The patient made an uneventful recovery.

CASE 8—F R, a white woman aged 62 was operated on for calculous cholecystitis and choledocholithiasis Oct 15 1936. A cholecystectomy was performed but owing to the fact that the patient could not stand any further operative procedure the stones in the common and hepatic ducts were not removed. After the operation the patient had three attacks of severe abdominal

Fig 4 (case 4)—Stepladder levels and marked dilatation of the coils of small intestine after administration of barium sulfate through a duodenal tube.

body type were occasionally seen. The child has now grown into a perfectly healthy young woman with normal bowel movements and normal general development.

CASE 11—M O C, a white man aged 42, gave the following history. In 1912 he was operated on for acute appendicitis and in 1915 for incisional hernia and was also treated for a peptic ulcer. About 1920 he began to have attacks of severe abdominal pain just above the appendix scar. The pain usually came on after eating, it started with a grinding sensation radiated up to the right upper quadrant and was relieved by one or more

enemas. The attacks had been more or less constant the past five months. He was advised that the removal of some infected teeth would help him. The teeth were extracted, but the attacks continued.

While the present condition indicated an inflammatory or obstructive lesion about the cecum, the history and the radiation of the pain made an examination of the gallbladder and the gastro-intestinal tract advisable. Cholecystography showed a

Fig 5 (case 9).—A, large stone in the gallbladder (film taken without dye Jan. 11, 1932). B, stone no longer visualized in the gallbladder region (flat film of abdomen April 14).

somewhat faint shadow with a mottled appearance, but a definite roentgenographic diagnosis of cholelithiasis could not be made. A series of gastro-intestinal roentgenograms gave essentially negative results. On aspirating the fasting stomach preliminary to a biliary drainage numerous blackish particles were found. The microscopic examination of these particles showed numerous cholesterol crystals (fig. 6), the significance of which was emphasized by one of us in a previous article.²

A diagnosis of postoperative adhesions involving the cecum as well as calculous cholecystitis was made and surgical intervention advised. The operation revealed rather dense adhesions between the omentum and the anterior abdominal wall in the region of the old scar. There was also found a definite elongated strand holding the cecum to the anterior abdominal wall, with a large opening beneath it which had allowed a loop of ileum to become caught in it. Two large stones and numerous blackish particles similar to those observed in the fasting gastric contents were found in the gallbladder. These particles were likewise composed of cholesterol crystals (fig. 7). A cholecystectomy as well as a freeing of the cecum was performed.

CASE 12.—E. S., a white man aged 35, was perfectly well until three hours after eating corned beef and cabbage, when he was seized with severe generalized abdominal pain accompanied by nausea and vomiting. The pain subsequently settled over the right lower quadrant. Tenderness was present over the appendix and the cecum although no rigidity or muscular resistance was felt. The temperature was 99.5 F. and the blood count showed white cells 7,200, polymorphonuclears 60 per cent, lymphocytes 29 per cent, mononuclears 1 per cent and eosinophils 10 per cent. Although appendicitis was suspected it was thought advisable to observe the patient further in view of the blood count and the absence of fever and local muscular resistance.

The next day the abdominal pain subsided and urticaria with giant hives appeared all over the patient's body. The eosinophil at this time dropped to 1 per cent. The following day jaundice developed with the following index: bilirubin 1.25. This jaundice was treated with a course of sodium sulfide. The patient was fully treated by means of a course of sodium sulfide. The tests never revealed a

edema with visceral manifestations, as originally described by Osler,³ who stated that in such cases a laparotomy was not infrequently performed.

CASE 13.—M. S., a man, aged 37, complained of periodic attacks of pain in the epigastrium which radiated to the right lower quadrant and which had been diagnosed as chronic appendicitis. The pain was followed in from one half to one hour by a rash over the buttocks, which itched greatly. The pain and the rash usually lasted about ten or twelve hours. Scratch tests showed positive reactions to lettuce, celery, egg white, salmon, onions and tea. When the patient did not eat these foods, he was symptom free. Recently he was seized with a very severe attack in the appendical region followed by the rash. When he was seen the next day no evidence of appendicitis was found. On questioning it was learned that he had eaten onions the night before.

CASE 14.—D. S., a white woman aged 29, first seen Nov. 28, 1932, had had periodic attacks of pain in the right iliac fossa for two years. One year before the appendix was removed in the hope that this operation would cure her. Six months later the pain recurred. She felt better when she ate strained vegetables but as soon as she returned to a normal diet her pain recurred. The pain usually came on about four hours after meals and at times during the night. She was very constipated and had to resort to enemas. She also complained of dizziness, fatigue and headaches. Physical examination gave essentially negative results except that it showed tenderness over the cecum. The blood pressure was 100 systolic, 70 diastolic. The blood count and the urine were normal. The blood cholesterol content was 111 mg. per hundred cubic centimeters of blood. A series of gastro-intestinal roentgenograms revealed pylorospasm but no ulcer. A barium sulfate clisma showed evidence of spasm of the cecum and the descending colon.

Ultraviolet treatment and injections of hydrous wool fat to elevate the blood cholesterol were given as advocated by Leopold and Bernhard⁴ and Berman.⁵ A high vitamin, high caloric diet and irradiated oil orally and by rectum were also prescribed.

Fig 6 (case 11).—Numerous cholesterol crystals together with a slight amount of calcium bilirubinate pigment (preoperative specimen of fasting gastric contents).

The blood cholesterol content rose to 175 mg. per hundred cubic centimeters of blood. The patient has been symptom free since the treatment took effect.

COMMENT

Patients with lesions of the right lower quadrant not infrequently present varied clinical phenomena.

3. Osler, W. M. D. On the Surgical Importance of the Vascular Crises in Erythema Group of Skin Disease. *Am. J. Med.* 3: 754 (April) 1904.
4. Leopold, J. S. and Bernhard, A. *Arch. Internat.* 46: 1929.
5. Berman, Louis. *M. J. Clin. Res.* 80: 123 (Aug. 7) 1929.

which make them difficult diagnostic and therapeutic problems. In the main they may be divided into those with acute and those with chronic conditions. It is generally acknowledged that in most patients with acute symptoms referable to the right iliac fossa an inflammation of the appendix proves to be the etiologic factor. However, the principal diagnostic and therapeutic diffi-

Fig 7 (case 11)—Cholesterol crystals together with calcium bilirubinate pigment (particle removed from gallbladder postoperatively)

culties arising in patients with lesions of the right lower quadrant are usually encountered in patients giving a history extending over months or years. It is unnecessary to dwell on the errors made or on the needless exploratory operations so often performed. Doubtless most of us at some time or other have shared the responsibility.

We would, however, like to emphasize certain facts in connection with this paper. A careful and painstaking history and a thorough physical examination are still of paramount importance even though marked progress has been made in the diagnostic aids which the laboratory has furnished. Furthermore, while an investigation of the gastro-intestinal tract by the usual routine procedures may reveal the lesion, negative results do not always rule out the existence of a pathologic process. Coexisting abdominal disease must also be borne in mind.

We do not believe in repeatedly subjecting the patient to the same gastro-intestinal studies when negative results are reported. Here special diagnostic procedures should be emphasized. A more frequent study of the small intestine as a means of detecting lesions of the terminal part of the ileum and the cecum should be encouraged.

The surgical treatment of lesions of the right lower quadrant will vary as to the pathologic process found. If, however, a definite preoperative diagnosis is made, the surgeon can map out a more comprehensive method of attack. His technic will be surer, surprise conditions at operation will be fewer and the risk to the patient will be much less. The presence of a diseased appendix always demands its removal.

At present there is no standard surgical procedure for the treatment of regional ileitis. The condition may present such varied clinical manifestations that it should

be suspected whether or not the appendix has been removed. If the appendix is still present an appendectomy should be performed at the primary operation when feasible. If abscess formation is found, simple drainage is indicated. If marked inflammatory edema is present, an ileocolostomy with short-circuiting of the affected part by means of healthy intestine well away from the lesion, is to be preferred, with possible subsequent resection. A primary resection is elected by some surgeons. At times an intestinal fistula then results, probably from lack of removal of all the affected area.

In cases of malignant disease of the cecum and the ascending colon, the presence or absence of edema and infection has a deciding role in the type of operation indicated. Our preference is for the one stage resection with ileocolostomy, when possible. If, however, this procedure is inadvisable, the two stage procedure is done or the operation as advocated by Lahey.⁶

All surgeons recognize the fact that marked inflammatory lesions in the ileum and the cecum may give a clinical and operative picture resembling malignant disease. Under these circumstances conservative surgical intervention is judicious.

SUMMARY

- 1 Lesions of the right lower quadrant often present diagnostic and therapeutic problems.
- 2 Special diagnostic methods are essential if routine gastro-intestinal examinations do not reveal a lesion.
- 3 Thorough study of the patient will prevent diagnostic errors and a needless exploratory operation.
- 4 Every lesion of the right lower quadrant does not necessarily require surgical treatment.

ABSTRACT OF DISCUSSION

DR ERNEST H. GAITHER, Baltimore. The information presented by the authors proves that if one is sufficiently versatile and persevering in the presence of atypical and puzzling syndromes, one will in most instances avoid the pitfalls which await the unwary whose first and last thought on the subject is that most lesions in the lower right quadrant are due to appendical involvement. My experience has been much the same as that of these contributors. In each case, the pathologic condition could easily have been discovered by interested and painstaking study of the symptoms and application of clinical investigations which are available to all and the patient might thus have been spared weary months of pain and discouragement. I am glad to say that after the discovery of the lesion each of these patients made a brilliant recovery. It would be most helpful to remember that a rich nervous supply places the alimentary tract and its changes under the influence of multitudinous impulses coming from all parts of the body. Hence it is most important to study each case in its entirety to distinguish between intrinsic abdominal disorder producing local symptoms, and extrinsic disease producing symptoms referred to various parts of the abdomen, notably the lower right quadrant. In this paper interesting instances have been presented of terminal ileitis, diverticula of the cecum, adenocarcinoma of the colon at the ileocecal junction, acute intraperitoneal abscess, acute gangrenous appendicitis and choledocholithiasis, intestinal obstruction in the terminal ileum due to gallstones and other lesions. It is this type of painstaking investigative diagnostic acumen, which can be developed by all physicians that leads to true progress in clinical medicine. That this progress in diagnostic certainty involves the amelioration of most of the ills of suffering humanity is not the least of our reasons for seeking to establish it.

Clinical Notes, Suggestions and New Instruments

PELLAGRA SUCCESSFULLY TREATED WITH NICOTINIC ACID A CASE REPORT

DAVID T. SMITH, M.D. JULIAN M. RUFFIN, M.D.
AND
SUSAN GOWER SMITH, M.A.
DURHAM, N. C.

It is well known that liver and certain of its extracts are highly effective in the treatment of canine blacktongue and human pellagra. Recently, Mueller¹ and Subbarow² have isolated nicotinic acid from liver. Elvehjem and his associates³

Fig. 1.—Horn concretions in the skin of the sebaceous glands. The projections on about the edge of the nose were present over the entire nose face and forehead but do not appear in the rest of the illustration because they are out of focus.

isolated nicotinic acid amide from liver and showed that pure nicotinic acid (Eastman) would cure experimental blacktongue. This observation has been confirmed by Dann⁴ and by Margolis and his co-workers. The latter found that nicotinic acid in dose of 15 mg. per kilogram of body weight was highly effective in curing blacktongue in dogs and harmless whether administered orally, intramuscularly or intravenously. We have recently had the opportunity of using nicotinic acid in the treatment of a man with a very severe case of pellagra with results so satisfactory that we feel that the case should be recorded.

REPORT OF CASE

W. H. B., a white male farmer, aged 42, weighing 41 Kg., was admitted to Duke Hospital Oct. 20, 1937, with a history of

recurrent pellagra over a period of fifteen years. His present attack began in the summer of 1937 with glossitis, diarrhea, dermatitis and mild intermittent dementia. His diet has been grossly deficient but there was no history of alcoholism.

The patient was emaciated, dehydrated chronically and intermittently disoriented. The tongue and buccal mucous membranes were slightly reddened but there was no definite papillary atrophy. A typical dermatitis was present on the hands and feet. The orifices of the sebaceous glands on the entire face were plugged with horny concretions (fig. 1). The remainder of the examination revealed nothing of significance except the absence of the abdominal and cremasteric reflexes. Hemoglobin was 13.6 Gm. (87 per cent), red blood corpuscles numbered 4,100,000. Urinalysis was normal. The electrocardiogram showed low upright T waves in all leads.

The patient was fed a basic diet, deficient in the pellagra preventive factor throughout his entire period of study. At the end of the first week it was obvious that he was becoming progressively worse. He refused to eat because he became completely disoriented and developed delusions of persecution.

Treatment was limited to nicotinic acid (Eastman) the patient remaining on the basic diet. A solution was prepared in sterile physiologic solution of sodium chloride so that 1 cc. contained 2 mg. of nicotinic acid. On the seventh day after admission the patient was given intramuscularly 60 mg. of the drug. On the next day he received intravenously 60 mg. dissolved in 1,000 cc. of 5 per cent dextrose in saline solution. For the next six days he received 60 mg. daily, the intramuscular and intravenous routes being alternated. On one occasion he was given intramuscularly 60 mg. dissolved in 6 cc. of physiologic solution of sodium chloride. On two successive

Fig. 2.—Same patient twenty days after photograph reproduced in Fig. 1 was taken and thirteen days after the beginning of treatment.

days 60 mg. was dissolved in 100 cc. of water and given orally. He was given in all 720 mg. of nicotinic acid.

No reaction followed the oral administration of the drug, however a marked flushing of the face, neck, chest and arms appeared a few minutes after intramuscular injection and lasted for fifteen minutes. This same flushing was observed after the patient had received intravenously about 200 cc. of the

6. Ruffin, J. M. and Smith, D. T. A Clinical Study of the Potency of Various Extracts of Liver in the Treatment of Pellagra. *South M. J.* 30: 4 (Jan.) 1937.

or approximately 12 mg, but slowly faded even though the injection was continued. The pulse respiration and blood pressure were unaffected and the patient experienced no discomfort except a slight feeling of warmth. The intramuscular injections were well tolerated even in high concentration.

The results of this treatment were dramatic. There was a striking improvement in the appetite within twenty-four hours. The mental confusion began to improve after forty-eight hours and he was entirely rational after six days of treatment. Within three days a definite change was noted in the appearance of the skin of the face, and after twelve days the skin was entirely normal (fig 2). On the seventh day of treatment there was a striking change in the electrocardiogram the T waves having returned to normal. On the twelfth day it was noted that the abdominal and cremasteric reflexes were present.

COMMENT

If subsequent investigations prove that nicotinic acid is the P-P factor of Goldberger, it would seem that the problem of the prevention and cure of pellagra have been greatly simplified. Nicotinic acid is very cheap, it cost less than 10 cents to treat this patient. It is possible that it could be mixed with table salt and sold in areas in which pellagra is endemic, similarly to the distribution of "iodized" salt in the districts in which goiter is prevalent.

SUMMARY

A patient who had endemic pellagra with anorexia, dermatitis, sebaceous gland changes and dementia made a dramatic recovery after the administration of nicotinic acid in doses of 60 mg daily for twelve days.

MAGGOT THERAPY IN AN INFECTED WOUND IN HEMOPHILIA

FREDERICK J. POHLE, M.D., AND STEPHEN MADDOCK, M.D.
BOSTON

The treatment of infected wounds in hemophilia is a tedious process requiring caution because of the continual danger of hemorrhage. Certain medications, especially oxidizing agents are frequently contraindicated because of this danger. Recently we have employed maggots in the treatment of a large infected wound in a severe case of hemophilia. The wound healed rapidly without hemorrhagic complications. The literature does not refer to maggot therapy in hemophilia.

REPORT OF CASE

I G, a Jewish youth, aged 19, single, admitted to the hospital Jan 18, 1937, complained chiefly of "swollen knees." The first evidence that he was a "bleeder" occurred at the age of 6 years when a small cut on the buccal mucous membranes bled continuously for twelve days. The condition was diagnosed as hemophilia at that time. However aside from a tendency to easy bruising and slightly prolonged bleeding from minor injuries he remained free of any critical episodes until the age of 13 years. The temporary teeth were lost without excessive hemorrhage except in one instance. For the past six years he had had frequent hemarthroses involving the knees, ankles and elbows. Five years before admission an attempt to correct forcefully a flexion deformity of the left knee resulted in severe hemorrhage which was controlled only after three blood transfusions. Shortly after this a hemorrhage developed in the muscles of the left calf. The skin broke down over the posterior aspect of the leg and an extensive infected wound followed. Although under constant care of physicians this wound did not completely heal for one year. Two years before admission the patient suffered from renal pains and there was hematuria on two occasions. There has been no hematemesis, melena, hemoptysis or epistaxis. He had had repeated hemorrhages into both knee joints for the past six months and had not walked for five months. He had scarlet fever in a mild form without complications four years before admission. The weight had remained quite constant at 150 pounds (68 Kg.) for seven years. The family history is completely known up to and including

the four grandparents and is negative for hemophilia. The mother died at the age of 50 of agranulocytic angina. The father, aged 58, is living and well. The patient has one brother, aged 29 living and well and without bleeding tendencies. He has one sister aged 33, who is married and has three sons and one daughter none of whom display a hemorrhagic tendency. All have normal blood coagulation times. The mother of the patient had one brother and two sisters. One of these sisters has a son who is not a "bleeder." All four grandparents are deceased and none are known to have had abnormal bleeding tendencies.

On physical examination the patient was well developed and well nourished. The head, eyes, ears, nose and throat were normal except that the tonsils were enlarged and cryptic. The lungs were clear and the heart was normal. The blood pressure was 128 systolic, 80 diastolic. Nothing abnormal was found on examination of the abdomen, genitalia or rectum. Neurologic examination was negative. Both knee joints showed a moderate effusion with restricted motion because of pain. There was a linear white scar 15 cm in length on the left calf, which was bound to the underlying tissues. The muscles of the right calf were hard and indurated as a result of an old intramuscular hematoma.

On admission the red blood cells were 5,140,000 per cubic millimeter, hemoglobin 14.5 Gm per hundred cubic centimeters, and the hematocrit reading 42.1 per cent. The white blood cells were 8,150 per cubic millimeter and the differential count was normal. Urinalysis and examinations of the stool revealed nothing abnormal. The Hinton test of the blood was negative. The coagulation time determined by placing 2 cc of venous blood in a 100 by 13 mm test tube at 37.5 C was 125 minutes on admission. Clot retractility was normal. The bleeding time was two minutes (Duke's method). The platelet count was 302,000 per cubic millimeter. The patient's blood group was B. X-ray examination of the knees showed a chronic degenerative arthritis.

The patient was confined to bed and the knees were treated with radiant heat and active and passive exercises. February 4 there was a spontaneous recurrence of hemorrhage into the muscles of the right calf. The leg was elevated, immobilized and packed with ice. Opiates were required for the relief of pain. The bleeding was apparently stopped by two transfusions of whole citrated blood, 300 cc twenty hours after the onset of hemorrhage and 200 cc twenty-four hours later. At this time the right lower leg was approximately three times larger than usual. As a result of circulatory stasis a marked edema developed in the right foot and ankle. The sensations and temperature of the foot remained normal. An ecchymotic area developed over the popliteal space. Several large blisters containing brown fluid formed over the posterior aspect of the leg. As a result of the hemorrhage the hemoglobin dropped from 14.5 to 9.2 Gm per hundred cubic centimeters in spite of the two small blood transfusions. The icterus index temporarily rose to 10. The anemia decreased with iron therapy.

The leg was dressed with sterile precautions daily and care was taken to avoid pressure over the tensely swollen portion. The blisters did not rupture until the twelfth day after the hemorrhage. From this time the open lesions continued to discharge large amounts of blood tinged serous material. In spite of various local treatments a deep denuded area measuring 6 by 15 cm developed over the calf region. There was a smaller lesion 2 cm in diameter in the popliteal space that refused to heal. Both lesions were filled with old blood clots and a low grade infection was present. It was felt that the breakdown of tissue was due to pressure necrosis from the inside. Because of a 25 degree flexion deformity of the knee and a weakness of the dorsiflexor muscles of the right foot, baking and massage were started to the knee and electrical stimulation was begun for the drop foot.

Because of the lack of healing in the infected wounds and a daily fever of from 100 to 102 F, maggots were first placed in the wound five weeks after the hemorrhage. Dressings were changed daily and additional maggots added as necessary. During the next week all the old blood clot and much of the necrotic material had been removed by the maggots. The temperature dropped to normal. The gastrocnemius muscle was exposed and the wound at this time measured 45 cm in depth. It was undermined from 3 to 5 cm in all directions.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard) and the Surgical Research Laboratory, Fifth Surgical Service (Harvard), Boston City Hospital, and the Departments of Medicine and Surgery, Harvard Medical School.

Maggot therapy was continued for four weeks. The skin layer healed to the muscle tissue, leaving two long narrow sinuses. Healing might have been hastened if it had been feasible to expose these sinus tracts surgically. Nevertheless, during the four weeks that the maggots were used, the infection entirely cleared up and the wound healed rapidly. At the end of this period a clean granulating area measuring 1 by 5 cm remained. This healed completely in two weeks with the application of warm boric acid packs. At no time during maggot therapy was there any evidence of bleeding, although the healing tissue was extremely vascular. Throughout this period the coagulation time of the blood was never less than two hours and varied between 122 minutes and 188 minutes. The patient became ambulatory and was discharged from the hospital May 8.

SUMMARY

In a case of hemophilia with an extensive wound resulting from necrosis of a hematoma maggot therapy was used with rapid clearing of the infection and resultant healing without any complicating hemorrhage. Five years before this patient had an almost identical lesion on the opposite leg resulting from the same cause. This wound did not completely heal for one year, while the lesion reported here healed in three months. Apparently maggot therapy may be used in wounds in hemophilia, after the cessation of active bleeding, without danger of hemorrhage.

Medical Society of the State of New York and the New
York State Department of Health

The Early Clinical Diagnosis of Pneumonia

DR. WILLIAM S. McCANN, Rochester, N. Y. Recent advances in the treatment of pneumonia yield dramatic results with certain types of the disease, notably type I. In the records of the Strong Memorial Hospital cases of type I pneumonia treated in the first ninety-six hours had a mortality rate of 11 per cent as contrasted with 44 per cent in cases treated later than ninety-six hours, and 4 per cent of all cases of pneumonia in which treatment was given. The advantage of beginning treatment in the first day is clearly apparent. The early clinical diagnosis of pneumonia is of such importance that each day that the diagnosis is delayed increases the mortality rate. The early diagnosis of pneumonia is of such importance that each day that the diagnosis is delayed increases the mortality rate. The early diagnosis of pneumonia is of such importance that each day that the diagnosis is delayed increases the mortality rate.

Signs of pneumonia in the lung are almost never present at the onset and may not be present in characteristic form for from twenty-four to forty-eight hours or even longer after the onset. In textbooks the sudden onset with a chill is greatly emphasized. While a sudden and characteristic of at least twenty-four to forty-eight hours or even longer after the onset. In textbooks the sudden onset with a chill is greatly emphasized. While a sudden and characteristic of at least twenty-four to forty-eight hours or even longer after the onset. In textbooks the sudden onset with a chill is greatly emphasized.

The ratio of the initial rapidity of the grunting breath-finger pain in the lungs involved, and limitation of respiratory movement on the side involved is an early phenomenon. The decubitus is important. The patient tends to lie on the side of the invasion and almost invariably lies flat. The presence of orthopnea is presumptive evidence against the diagnosis of pneumonia. In such a case the true diagnosis is far more likely to be infarction of the lung. The percussion note and fremitus rarely give consistent evidence during the stage of invasion of the lung. On auscultation the breath sounds over the involved areas may show simply a diminished vesicular murmur, later complete suppression of the breath sounds over certain areas with bursts of fine crepitant rales on inspiration after cough.

The important early clues to a diagnosis of pneumonia would list in the order of their constancy and reliability as follows: 1 Character of breathing, dilated alae on inspiration, rapid, shallow expiratory grunt, low pulse respiration ratio 3 to 1 or 2 to 1. 2 Cyanosis. 3 Dyspnea, cough, pain in the side. 4 Localized limitation of respiratory movements with suppression of breath sounds and frequently fine crepitations. 5 Character of the sputum, blood cells and leukocytes and pneumococci. 6 Onset with rigor. 7 High degree of leukocytosis. Pneumococci of type I or type II are rarely present in healthy persons. When these types are found in blood-tinged sputum there is little reason to doubt the existence of a pneumococcal infection. Organisms of type III and group IV are not uncommonly found in the throats of healthy persons. Their presence in sputum has less significance as primary causative agents in pulmonary disease. In my opinion, x-ray examination is of little value in the early diagnosis of pneumonia. It may be important in differential diagnosis in doubtful cases and special conditions which I shall refer to under differential diagnosis. In true pneumococcal pneumonias the use of the x-ray examination is quite superfluous in the early stages, and valuable time should not be wasted on it as a rule.

As the invasion of the lung progresses, the typical signs of consolidation may be heard at the periphery of the lung in one part sooner than another. Before frank signs of consolidation appear, however, dullness may increase, the character of the whispered voice transmission assumes a bronchial quality, and the rales heard have a consonating quality and seem to be close to the ear. In case of invasion of a new lobe when one lobe is already consolidated the temperature, which has been previously elevated, may drop for a few hours. During this drop the patient exhibits some evidence of shock, the pulse may accelerate, the blood pressure fall, the respirations increase. Cyanosis returns. Suppressed breathing and rales may recur over the new lobe. The temperature after a temporary fall rises again. When such evidence of new invasion occurs the sputum should be retyped. Necropsy sometimes reveals different types of pneumococci in different lobes. This should remind one that patients with pneumonia should be protected from infection with other types of pneumococci introduced by visitors, attendants or nearby patients and make one alert to use specific serums on bacteriologic evidence obtained at each new lobar invasion, whatever the initial type of pneumococcus.

Too much effort should not be wasted in differentiating between lobar pneumonia and bronchopneumonia. A common mistake is to confuse large pulmonary infarcts with lobar pneumonia. The points to remember are that infarcts of the lung are usually found in orthopneic patients. The sputum with infarction is frankly bloody from the start. Fever, leukocytosis and signs of consolidation occur with infarcts, and the physical signs develop more rapidly than in pneumonia. Cyanosis is usually more profound than in a pneumonia with corresponding amounts of consolidation. The diagnosis usually depends on recognition of the associated heart disease or phlebitis from which the infarction originates and the coexistence of orthopnea. should always raise doubt if a diagnosis of pneumonia has been made. The differential diagnosis between pneumonia and pleural effusion occasionally gives trouble. In case of doubt aspiration with a needle will settle the matter. Fluid displaces the heart to the opposite side. Massive atelectasis displaces the heart toward the atelectasis. Massive atelectases may be accompanied by pneumococcal infection. I have seen three types of pneumonias with atelectasis occur in the same lobe in a patient with aneurysm and compression of the bronchus to the lobe. In case of doubt between massive atelectasis or pleural effusion

and pneumonia it is always safe to study the sputum and give serum if a specific type I or II pneumococcus is present. The discussion of differential diagnosis should not overlook the signs of consolidation frequently found in the lung in acute rheumatic fever. These arise in several ways: (1) by compression of the left lower lobe posteriorly by fluid in the pericardial sac, (2) by pleural effusions and (3) by rheumatic arteritis with congestion and atelectasis. There is no such thing as rheumatic pneumonia. Here again doubt will be resolved by study of the sputum itself and by recognition of other features of acute rheumatic fever. In differential diagnosis chest roentgenograms may be of use. Recourse to roentgenology may be had at any time. However, I cannot visualize a situation in which it would take precedence over a careful physical examination and the study of the sputum itself. The collection of sputum is occasionally difficult. In children it may not be expectorated. It is frequently possible to get it on a piece of sterile gauze over a gloved finger inserted well back in the pharynx. In this discussion I have not emphasized the importance of taking a blood culture. I do not mean to convey the idea that I regard blood cultures as of little value. Quite the contrary. I have been more concerned with the early phenomena which would lead to suspicion of pneumonia and which would lead the physician to have sputum and blood culture done, leaving the discussion of these procedures to the next speaker.

DISCUSSION

DR EDWARD S. ROGERS, Albany, N. Y. All are probably aware that in connection with the pneumonia program of the Bureau of Pneumonia Control of the State Department of Health for the past two years there has been a fair amount of general lay educational activity. We are not, of course, attempting to teach the public how to diagnose pneumonia. We do feel that before the methods of treatment which we have can be applied we must be reasonably sure that laymen will consult the physician early in the disease. Therefore we have selected that group of symptoms which are more typical and which the layman should be able to recognize—namely, the chill, pleurisy, rusty sputum and fever. Any one of these four, we are telling them today, are of themselves sufficient indication for calling a physician at once. We are laying particular stress on the development of these symptoms with a preceding story of upper respiratory infection.

The Bacteriologic Diagnosis of Pneumonia

DR J. D. GOLDSTEIN, Rochester, N. Y. The pneumococcus causes by far the majority of all pneumonias. A discussion of the etiology of the pneumonias implies a discussion primarily of the pneumococcus. Morphologically the pneumococcus is a gram positive ovoid organism which on the stained slide may appear in pairs or in short chains. Originally the pneumococcus was put in the streptococcus group and as it is examined under the microscope one may not be able to differentiate the two. There are, however, certain bacteriologic criteria by which this differentiation can be made. One is the presence of a capsule on the pneumococcus; the other is that the pneumococcus is bile soluble. In addition, it is possible to recognize the organism by its colony growth on blood agar. It is known that pneumococci differ antigenically; in other words, there are different types of pneumococci. This was suggested over thirty-five years ago by Neufeld. With the impetus of the large number of pneumonias seen during the war period, Dochez and Avery were able to separate out three definite types, I, II and III, and a large group, the so-called group IV, in which were placed all those not in the first three types. From 1929 to 1932 Dr Georgia Cooper and her associates defined twenty-nine types of pneumococci in group IV. These types were just as distinct as the previously recognized types I, II and III. There is a very small amount of crossing of these types, as for instance between types III and VIII, II and V, VII and XVIII, and XV and XXX. This crossing is not of significance as the methods of identifying the separate types are adequate to differentiate them.

The classification depends on the type of carbohydrate substance which the organism contains. This carbohydrate is present in the capsule. The details of this phase of the problem were clarified through the work of Heidelberger, Goebel

and Avery. It is known now that the pneumococcus contains two fractions: the carbohydrate fraction contained in the capsule and the protein fraction in the body of the organism. Type specificity depends on the carbohydrate substance in the capsule. The distribution of pneumococci is of importance. In different years one will find a preponderance of a particular type of pneumococcus. The preponderant type will also vary in different communities in the same year. In Rochester we have a list of 805 typings from October 1935 to October 1936, and from this table one can get an idea of the distribution of types for this period. During this period type I was found ninety-one times, type II fifty-nine times, type III 162 times and all others 493 times. In general, it is worth noting that between 55 and 60 per cent of pneumonias are usually due to types I and II, about 35 per cent of type I and from 20 to 30 per cent of type II.

Pneumococci of types I and II are rarely found in the throat of a normal person. This, however, is true only in a limited sense. Types I and II and other types of virulent pneumococci are found in the throats of many normal persons who have been in contact with known cases of pneumococcal infection—not only of lobar or bronchial pneumonia, but of any type of pneumococcal infection. The discussion as to whether or not there is a carrier stage has been answered definitely. Carriers of virulent pneumococci do exist, usually in contact with a known case of pneumococcal infection.

One must know the type in order to be able to use the serum that is indicated. That is the obvious reason for the impor-

Occurrence of the Various Types of Pneumococci

Type	Type	Type	Type	Type	Type
I	91	IX	18	XVII	22
II	59	X	7	XVIII	10
III	162	XI	13	XIX	25
IV	13	XII	21	XX	20
V	36	XIII	14	XI	9
VI	26	XIV	18	XII	11
VII	27	XV	5	XIII	10
VIII	64	XVI	5	XIV	13
Total					501

tance of typing. The importance of early typing will be just as obvious from the following papers and from what Dr McCann mentioned. The mortality is directly in relation to the speed with which one gets serum to the patient. This has been statistically proved repeatedly, and I think it can be said that it is an accepted fact. If serum is given early, good results will be obtained.

What about the methods of typing? Since 1902 a method has been written into the literature which is now preferred. Neufeld in 1902 wrote that when a pneumococcus is injected into a rabbit and an antiserum is produced and then the pneumococcus is mixed with the serum the pneumococcus changes in appearance by becoming much swollen. He was able to identify the organism by this reaction. In 1932 Armstrong, Logan and Smeal in England and in 1933 Sabin in this country again worked with this technique, the so-called Neufeld or quellung reaction. It is a simple test: a drop of sputum, a drop of dye and a drop of serum examined microscopically. The preparation is examined in five or ten minutes and one either does or doesn't see the reaction. It is specific. It is 90 per cent efficient, as checked by the reliable and relatively absolute mouse method.

What procedure should one follow when a person suspected of having pneumonia is admitted? This may be heresy, but I say that to do typing alone and depend on the quellung reaction alone requires a certain amount of unjustifiable courage, particularly if one is not acquainted with the test. The people who work in laboratories expect an error of from 5 to 10 per cent in working with the quellung reaction. They check themselves by repeating the test and by further procedures. Therefore the ideal thing to do with a sputum specimen is to send it to a laboratory, which is best equipped to do this type of work.

We use a blood culture as a reasonably good prognostic index, and we use the blood culture as a reasonably good

criterion for the intensity of treatment. We don't always think of it as a typing method yet it may be the only method that will work. One other important advantage about the blood culture should be obvious, when one has a type III sputum report and a type I blood culture report, obviously one thinks of and uses the type I serum. Mixed infections do occur. A mixture is not infrequent. The blood culture is obviously of importance as a typing method as well as a prognostic index. A thick, glairy, tenacious, slightly blood tinged sputum is best for a quelling reaction. In some patients one does not get sputum. The thing to do is to swab the throat as thoroughly as one can and see if coughing can be induced. In children it is worth remembering that sputum is swallowed and occasionally the stomach tube will produce a suitable sample for typing. One should get whatever sample one can and by all means persist in trying to get the sample. Speed is obviously essential, and the best way to get speed is to take advantage of the nearest laboratory. A blood culture should always be used. Finally, it is worth checking the typing. Our quelling reactions are checked by the macroscopic tube method. We find discrepancies. Not only will one check the inaccuracies of the laboratory by sending in a second sample of sputum, but there are mixed infections which may be so clarified.

DISCUSSION

DR. ROGERS: I think that probably all physicians have at their command many ways of treating pleural pain. Any means of relieving pleurisy enough so that the patient can make the necessary effort to cough up a good specimen will pay one for time and effort. Why do I say this? Because if one has to resort to taking a blood culture it will take from six to eight hours, probably, to get a report. Therefore, two or three hours spent in trying to get a sputum specimen would be to the advantage of the physician and of the patient. Furthermore, one can place more reliance on the report of the sputum specimen. On the use of opiates opinion is somewhat divided. I think that early in pneumonia the discreet use of codeine to relieve pain may be justifiable. The use of morphine has come in for a great deal of criticism probably well founded. Another point of practical importance is that if one has a specimen particularly in the middle of the night, one will save time by telephoning the laboratory from the patient's home before sending the specimen. The principal sources of error in typing are not going to be in positive reports from the laboratory but in negative reports. I think one might well be able to pick up IV report. If it is group IV and one has a blood culture of lobar pneumonia it is well to repeat the blood culture. The typical case of lobar pneumonia is more of the type for which we have serum. If the blood culture is negative it probably means that the patient did not receive a satisfactory specimen. Of course the blood culture and the specimen. The two together—serum and blood culture—proved the most accurate method generally available for typing, having perhaps lung suction which is not so easily applicable outside certain clinics. As a result of our first two years' study we found that in all the type I cases which had blood culture were done in hospitals only 30 per cent of the type I pneumonia in hospitals are having blood culture. There is a point to develop our blood culture further but the answer to that I don't know. I put it out as a question somewhat of a question and your thoughts on it will be more than welcome.

Oxygen Therapy of Pneumonia

DR. J. G. M. FELLOWS: New York. Not every patient needs oxygen but there are a few for its use. In pneumonia it is used in a fever and a temperature of 104 or 105. When one is resting and there is apillary suffocation consolidated lung this want without pneumonia and these circumstances. If one

wants to get more water out of a faucet than is able to pass through at a given pressure, one can increase the pressure. That is exactly what we do when we give oxygen. We increase the pressure of the oxygen at the interface. We give oxygen when there is an increase in the pulse rate an increase in the respiratory rate or an increase in the nervous irritability. At Harlem Hospital, where we cannot always observe the capillaries of the skin, we give oxygen when the pulse becomes 120 or when the patient is nervous and irritable.

Intravenous oxygen is dangerous. Subcutaneous oxygen is inefficient. It can be given with a catheter, a method which has many objections, although a catheter or rubber tube is always at hand. Then one can use an inhaler, a pronounced metal inhaler which just fits within the nostrils. Another method is to use a mask which fits about the face. Finally one can use either a tent or a chamber. Each of these methods has its place. Ordinary industrial oxygen best taken from the ordinary industrial tanks, is needed. A gauge is needed to show the rate at which the oxygen is being delivered. Finally one needs to know whether there is any oxygen remaining in the cylinder. There is also needed a method of moistening the oxygen, because dry oxygen is irritating to the nasal mucous membranes. How high must the gradient be in order that we shall have efficient oxygen therapy? All I can say is "enough" because what will be adequate for one patient will be utterly inadequate for another. Ordinarily the gradient is about 70 mm of mercury. That is partial pressure. We can lower the need for oxygen by lowering temperature either by skillful nursing, which means more rest, or even by the use of antipyretics, or we can supply enough oxygen. Ordinarily the venous blood contains 55 per cent, or 40 mm partial pressure of oxygen, and the arterial blood 1342 per cent, or 100 mm of pressure. In this room it is 21 per cent, or 160 mm. In the alveolar air it is 145 per cent, or 110 mm, so that the respiratory gradient is the distance between 110 and 40. In the expired alveolar air, when oxygen is being supplied by a nasal catheter at the rate of 4 liters a minute, there is 30 per cent oxygen in the alveolar air, or a pressure of 226 mm, and the respiratory gradient becomes 166 mm as opposed to what it was before, which was 70 mm. If a much more rapid flow, 80 liters a minute, is being used, the normal gradient has been increased at least fourfold. Oxygen in an ordinary commercial cylinder is adequate. There is no medical oxygen. Regulators are important, and there are two types. One type has a variable orifice and the other a fixed orifice. There are two ways of giving oxygen directly from the cylinder. There is a device which takes the oxygen just inside the nostrils and there is the catheter which carries the oxygen into the pharynx. Even writers who are most enthusiastic for the catheter admit that in 15 per cent of the cases they are unable to use it because the patient gags and rejects it. Patients do not reject the inhaler, because of the difference in the point at which the oxygen is discharged. Oxygen is accepted more readily when it is delivered to the mucous membranes of the nose rather than in the pharynx because the impact depends on the resistance and the size of the opening. It makes a difference whether the inhaler discharges the oxygen close to the mucous membranes or at a distance of 1 inch or an inch and a half because the pressure rapidly falls after it escapes from the orifice. With an expiratory flutter valve mask one can get a higher concentration of oxygen than with the catheter or nasal inhaler or even a well run tent or chamber. At 4 liters a minute one can get from 29 to 33 per cent oxygen in the alveolar air of a tent which was the same as a chamber gave from 35 to 39 per cent oxygen. At 6 liters we got from 42 to 42 per cent oxygen which was the same as a chamber carrying from 39 to 40 per cent. With 8 liters we could get exactly as good oxygen concentration as in a chamber. The purpose of a tent is to confine oxygen and when we confine the oxygen we also confine carbon dioxide, heat and moisture. We also stop or reduce the air circulation. It is thus necessary to provide an air conditioning adjunct to every tent. The great advantage of the chamber is that one can be with the patient. The great advantage of a tent is that there is no patient about the patient's face. The great advantage of the mask is that it can be applied to almost everybody, except those who are very sick or delirious and won't permit any device to

on the face, or patients with obstruction to their noses. Oxygen will never of itself, probably, cure a patient with pneumonia, but oxygen keeps the patient alive until his own mechanism or the serum brings about recovery.

I have encountered not infrequently commercial organizations that were selling oxygen equipment or providing rental service, who state that analyses have been shown to be unnecessary. That is absolutely untrue. Analyses should be made at frequent intervals. It is so simple that any really intelligent person in the home can be taught to carry it out. There is one thing ever to keep in mind in oxygen therapy and that is the hazard of fire from explosion. It is practically negligible if precautions are observed. Keep sparks of any kind away from the vicinity of the oxygen equipment. It is not advisable to go into an oxygen tent with electrical equipment that is liable to make a spark. Inflammable materials that are more liable to spontaneous combustion should be removed.

Serum Therapy of Pneumococcic Pneumonia

DR RUFUS I. COLE, New York. I have been able to study in the last few years more than 2000 cases of pneumonia. Certain cases of pneumonia are associated with pneumococci in the sputum, certain other cases are associated with streptococci and others with staphylococci, but little thought has been given as to when pneumonia is actually present. The trouble is not so much to differentiate pneumonia from other conditions such as aneurysms or fluid but to say when a patient actually has pneumonia. In at least 60 per cent there occurs a preceding upper respiratory infection, and finally the patient begins to expectorate sputum and the doctor is called in.

Pneumonia is an acute inflammatory disease of the lungs. Sometimes pneumonia can be determined only by x-ray examination. My associates and I have had 1,600 and some cases which we call lobar pneumonia. We have had 200 cases of streptococcic pneumonia, a smaller number of staphylococcic pneumonia, and so on. But when all these cases are taken away, there is still left a group of cases in which pneumococci were present but the symptoms and features which we consider as characteristic of lobar pneumonia were not present. Those cases we call atypical pneumonia. The term "atypical pneumonia" is a better term than "bronchial pneumonia" for pneumonia in which the symptoms and signs are not characteristic. It is probably better, however, that every case manifesting severe symptoms, in which there is pain, cough and, above all, bloody expectoration, should be called lobar pneumonia and should be treated as such. The epidemic of pneumonia that occurred in 1917-1918 was undoubtedly due to streptococci. In 1918-1919 there was a great increase in staphylococci. It seems rather unimportant and rather misleading, therefore, to think of pneumonia as being a fixed condition. That is why it is so difficult to determine the exact therapeutic value of any kind of treatment. Not only does the kind of pneumonia vary, but the severity is of various grades. It is only a few years since all forms of intestinal infections were called inflammation of the bowels. This included typhoid, the paratyphoid fevers, dysenteries and formerly appendicitis. It seems to me that the situation with regard to pneumonia is similar. There are one or two conditions in which the features are characteristic and definite and in which the disease is probably transmissible directly from patient to patient. Then there is a group of conditions in which the symptoms are much less constant, which appear widely in a community and then may disappear entirely. It is interesting that, in all these atypical forms of pneumonia in which pneumococci have been found present, in no case have type I pneumococci been present and in a very limited number of cases type II. The question has sometimes arisen whether these type II infections were not due to the so called II-a. When one talks, therefore, of the treatment of pneumonia one has to talk of the treatment of a large group of conditions, and the treatment may be very different.

Many years ago it was thought that if patients with type I pneumonia could receive large amounts of serum and receive this serum intravenously so that it could reach the locus of infection certain patients at least might be saved. This belief was based on experimental evidence, and it seems to me that

even today this evidence is of great value in helping one to decide for oneself whether or not one will use this method in the treatment of type I pneumonia. Animals, and especially rabbits, could be actively immunized against very large doses of type I pneumococci. Finally, they could be given doses thousands of times larger than the dose which would kill an animal not so treated. Then we found that the serum of these animals, when placed in the peritoneal cavity of mice, together with doses of culture much more than would kill a normal mouse, resulted in the mice being entirely free from any symptoms. Other mice receiving smaller amounts succumbed readily. So we began the treatment of patients with large doses of immune serum received from horses. This serum was given intravenously. It required a little courage at that time to treat patients with these very large doses given intravenously, and if one is a little worried today about giving serum to patients in small doses, one may think how much greater our trepidation was when we gave 100 cc of horse serum every few hours. But our experience soon showed that whereas many of these infected patients had previously had positive blood cultures, when the serum was given in large doses the blood cultures became sterile. That seemed to me more important than the fact that many patients recovered. Furthermore, the results so far as mortality statistics go have been most encouraging. Why we had to give such large doses of serum were at first obscure, but gradually it became evident, through laboratory studies just why it was necessary. Pneumococci are virulent only because they possess capsules, and these capsules in some mysterious way prevent the leukocytes from taking them up and destroying them. There are various methods now for getting rid of these capsules. Pneumococci of the most virulent type may be made to grow having no capsules whatever, and these pneumococci when injected into animals cause no infection, and when they are placed in mixtures together with leukocytes the leukocytes take them up readily and destroy them. But this capsular substance is set free, as is now known, in the circulating blood and fluids of the body. In the very ill patient the amount of this capsular substance in the blood may be very large. It frequently is excreted in the urine. When immune serum is added to this capsular substance, the so called antibodies of the serum become fixed by the capsular substance, and so the bacteria having capsules may be entirely unaffected by the immune serum. For instance, if one takes pneumococci, places them on a slide and adds a great deal of capsular substance to the surrounding medium, the amount of phagocytosis which occurs when the immune serum is added may be very slight. In the patient ill with pneumonia, before the pneumococci can be affected it is necessary that all the capsular substance in the body be attacked by sufficient serum so that there will be a surplus remaining after all the capsular substance has been united and fixed by the immune bodies. That is the reason why it is so important to give large amounts of serum. It is the reason why it is important to give the serum early in the disease, before large amounts of the capsular substance have been formed.

We have treated more than 500 cases of type I pneumonia with immune serum over a long period of years, and the results clinically have been uniformly satisfactory. In this series the mortality rate in the cases treated in the first three days has been under 48 per cent; in those treated on the fourth day it has been 8 per cent; on the fifth day, 8.6 per cent; on the sixth day, 19.5 per cent. It is therefore obvious that the earlier the patient is treated, the more satisfactory the results will be. Fortunately we have in New York State, I think, the best public health laboratory in this country and probably the best in the world. It has worked continually all these years on producing better serum—concentrating the serum. By that I mean removing the portions of the protein in the serum which are ineffective. As a result it has produced a serum which is concentrated at least three or four times. The methods of testing the serum have been greatly improved, although they are not ideal as yet because no method of testing serum can be perfectly satisfactory in which living animals such as the mouse must be employed which vary so much in their resistance and their susceptibility to disease. A method of deter-

mining the so-called immunity serum has been devised, so that we can tell with a considerable degree of accuracy just how much of the immune substance we are giving to patients. We have always given much more serum, I think, than any one else. Our dosage, when whole serum was employed, was 100 cc at first, and we continued that every eight hours until there was definite evidence that the serum was effective. We have sometimes given over 2 liters of serum to a patient with lobar pneumonia, in a number of cases with good results. We now give 90,000 units at the first dose and repeat this as often as necessary until the symptoms are alleviated. I think this is very important. There is no way of telling accurately when a patient has had enough serum, but there is one method which helps us very much, and that has been a method devised by Dr. Francis. This method, however, is not completely accurate. In certain cases in which there is a positive skin reaction it has been necessary to give more serum. Large doses of serum should be employed and they should be repeated and continued until definite signs of effect on the course of the disease are obtained. We are fortunate in now having in this state a large supply of serum which we can feel is effective and trustworthy.

Up to recently, most of the serum used in the treatment of pneumonia was derived from horses. During the last year a number of cases have been treated with serum made by immunizing rabbits actively to pneumococci. The rabbit serum theoretically should be effective, chiefly because it has been shown that the molecular size of the protein which represents the antibody, when derived from the rabbit, is very much smaller than that in the horse serum. This has been determined by methods of ultrafiltration. The rabbit serum also has been much cheaper to make than the horse serum. Thirty-two cases have been treated with the rabbit serum, and the clinical results, so far as one can judge from mortality, have been very satisfactory. The objection to the use of the rabbit serum is that the chills, which occur also following the administration of horse serum, occur with greater frequency and severity when rabbit serum is employed. Various methods have been used to get rid of this chill-producing substance. It has been found that by giving the patients acetylsalicylic acid just before the serum is administered the frequency and severity of the chills may be to a considerable extent reduced. We are now employing rabbit serum entirely with our patients, but I think this is a special problem one that should be undertaken in a special place under favorable circumstances until it can be determined whether or not rabbit serum is actually more effective than horse serum.

In the cases in our experience where the fever continues high where the respirations remain rapid and cyanosis continues after two or three days of serum treatment, we have found a serious complication such as endocarditis or meningitis. In the last fifty-one cases of type I pneumonia treated with concentrated horse serum and rabbit serum, not one of our patients has died. This, however, is a record which probably cannot be repeated. I think all the statistics indicate that if serum is effective in type II pneumonia, it is much less effective than in type I. This would be expected from the experimental evidence. It is much more difficult to produce an effective serum for type II and with such serum it is much more difficult to save animals highly infected. This was observed before we ever began treatment with serum, and the experimental evidence has been fully confirmed by clinical observation. However, some of the studies have indicated that the mortality rates in type II pneumonia may be reduced by the proper therapy and active use of type II serum. My own feeling is that every patient with type II pneumonia should receive serum, but the difficulties of treatment the necessity for a large amount of serum the necessity for constantly repeating the treatment. In the present than in the past few years I am told a large percentage of this type of pneumonia as in Scotland of type II

In New York, where previously we had as many as 15 per cent of the cases due to type II, there has been a distinct diminution. Last year we had only 11 per cent.

With regard to the other types in which serum is now provided—types V, VII, VIII and VI—these belong in the group in which the severity is much less. If we have a method by which the mortality may be reduced 3, 4 or 5 per cent it certainly is justifiable and worth while to employ the serum when the diagnosis can be made. In these cases probably the importance of giving continued large doses is not so great as it is in the case of type I and II pneumonia. I would stress the fact that in type I pneumonia large doses must be given they must be given often, and the doctor must see his patient frequently. When type II serum is employed still greater attention must be given to the patient, larger doses must be given and they must be given over a longer period.

The dangers of serum, I feel, have been to a certain extent exaggerated. After the administration of serum in a few cases, there may be immediate reactions in the form of collapse, respiratory collapse, and so on. The number of cases in which these symptoms are of great severity, however, is very small. In my own experience I have seen only three or four cases of severe anaphylactic reaction. Most of the reactions can be promptly controlled by giving the patient epinephrine in small or large doses as necessary. Serum reactions that occur following the administration of serum occur in a considerable number of cases. These, however, are not serious. They are distressing to the patients but the reactions which develop from forty minutes to an hour after the administration of serum are in most cases disturbing chiefly for the discomfort which they cause. The same may be said of the so-called serum disease. Patients complain a great deal about serum disease, and many patients say they would rather die of pneumonia than have serum disease. But when one compares the discomfort caused by this condition with the savings of life which occur from the proper administration of serum, it seems to me that serum sickness may be disregarded.

The chief points that I wanted to make in my talk are that the serum should be given very early, it should be given in large amounts, and its use should be continued as long as there is a chance of the serum affecting the outcome of the disease.

DISCUSSION

DR. ROGERS: Dr. Cole has made the point clearly as to why large amounts of serum are necessary, namely, that the circulating capsular substance in the blood stream must be neutralized by serum before it can get to the bacteria. It is equally important, therefore, to give the serum early before large amounts of this excess substance get into circulation. Not only should it be given in large doses, but it has been definitely indicated by our experience in the last two years that it is necessary to complete within a relatively short time. Extensively spread dosage should be avoided. Dr. Cole mentioned the intradermal test devised by Dr. Francis which unfortunately, because of its difficulty of interpretation is not a widely practical test. Dr. Bullowa has devised another test which is based on a temperature determination indicating the amount of circulating antiserum in the blood stream. We have accumulated data on almost 1800 type I cases treated with serum. About 35 per cent of that represents experience in the homes, not in hospitals. There has been but one death that we are definitely obliged to stamp anaphylactic reaction. There have been a larger percentage, 7 or 8 of moderate to severe reactions, but they have readily responded to appropriate treatment. If patients give a history of sensitivity a reaction may result. There are circumstances under which serum treatment is probably justifiable even though a reaction may be anticipated. The question of desensitizing is not a demic, but serum can be given with great care. In relatively minor degrees of sensitivity epinephrine should help. To some degree there is another consideration which places the patient in the category in which treatment is justifiable and that is pregnancy during the later months. That is distinctly a serious hazard. Dr. Cole mentioned the development of rabbit serum. My greatest fear is that if rabbit serum is used indiscriminately and reactions are encountered it will perhaps darken the future of serum therapy. It should be a very real and

when it has been perfected. There are at present a number of typing stations in the state. Type I serum is available in well over a hundred stations, and there are several providing type II. In the next few weeks we shall start distributing V, VII and VIII. We have, for instance, certain parts of the state where type V pneumonia is the major pneumonia, and there we shall provide type V serum. All are probably aware of the legislative appropriation for this purpose, which was made last spring. We did not get the money immediately, and it takes sometimes as much as a year to get a horse up to a point where his serum is satisfactory. As soon as possible, however, we shall provide our own serum. In the meantime we shall provide what we can and purchase the rest.

Pneumonia Clinic

DR ROGERS. The clinic this afternoon is to be conducted by Dr L A Kohn and Dr W W Fray. Dr Kohn will discuss the clinical side of the cases and Dr Fray will discuss the roentgenologic phases.

DR L A KOHN, Rochester, N Y. We are going to start off by showing a case of type I pneumonia.

Mr P, a carpenter, aged 38, was admitted to the hospital on the third day of what proved to be type I pneumonia. His past history was irrelevant. He never had pneumonia before. He had a cold ten days to two weeks prior to October 5, when on returning home from his work on an outdoor job he noticed that he had a little pain in breathing. The next day, October 6, he went to work but that evening felt really sick. His temperature was 101.4 F. He had a cough and pain on both sides of his chest on breathing. The next morning there were no signs in his chest. His temperature was 104. He had a chill and began to produce rusty sputum.

The morning of the third day of the disease, the day of admission to the hospital, the temperature was still higher, he raised more rusty sputum and the physician found definite signs of pneumonia. On his arrival at the hospital his sputum was taken in the emergency ward and sent to the laboratory and found to contain the type I pneumococcus. His temperature was over 105, the pulse was rapid, 120, and the respirations were rapid. The blood pressure was 110 systolic, 60 diastolic. He was slightly cyanotic, he was perspiring, his breathing was rapid and shallow. He was slightly jaundiced. There was physical evidence of a well developed pneumonia in the lower part of the right lung in back.

The white blood count was 31,000. Blood chemical studies revealed that the nonprotein nitrogen was 59. There was slight jaundice in the blood serum. The icterus index was 18. The blood chlorides were reduced to 517 as opposed to a normal of somewhere around 590. The urine was typical of the febrile patient.

Prior to giving serum, a blood culture was taken, and a careful history was taken to obtain evidences of allergy or previous experience with serums. The cutaneous test was done and the ophthalmologic test was done, and as both were negative 50,000 units of type I serum was given the patient that evening diluted to about 100 cc with sterile salt solution. Prior to this large dose 1 cc was given very slowly diluted to 10 cc by sterile salt solution and an interval was allowed to elapse before he was given the full initial therapeutic dose. There was no reaction to the small dose but forty-five minutes after the dose of 50,000 units he had a chill and his temperature rose to 106.2. He was given a tepid sponge bath, his temperature dropped and about four hours later he was given another 50,000 units. There was no reaction to the second dose.

The next day he received an additional 100,000 units. That made 200,000 within the first four days of the disease. His temperature had fallen not to normal but appreciably, without a critical sweat within the next twenty-four hours and as the blood culture had failed to show growth it was decided to give him no more serum.

By the sixth day of the illness there were distinct evidences of resolution in the right lower lung. The breathing was not so rapid and the general condition was improved. On the seventh day of the illness the white blood count dropped to 10,000 and with minor fluctuations it has remained normal.

This is the fourteenth day of the disease. In his chest at this time there are still a few coarse rales, but most of the dulness and I think all of the abnormal breath sounds have disappeared. He is still coughing a little.

[Here and at other points during Dr Kohn's talk, Dr W W Fray, Rochester, N Y, showed slides of the roentgenograms of the chest of the patient, describing evidences of the disease as shown in the roentgenograms.]

People who attended or examined this patient wore a mask and washed their hands when they left. We consider that all cases of pneumonia are communicable and that people should be protected from possible contagion. The patient was given an adequate amount of fluid and as much food as he could eat without causing further distention. He was given 6 Gm (90 grains) of sodium chloride in the form of pills daily, in addition to salt in his food. He was given mild sedatives to control his cough, and once or twice a small dose of morphine.

One topic that Dr Fray and I were asked to discuss was that of complications of lobar pneumonia. Of the serious complications of lobar pneumonia, or of pneumonia in general, the only one which can be distinctly influenced is empyema. There is only one sure way in the long run of diagnosing empyema and that is to find pus with a needle. Conversely, if one wants to be sure that there is no pus, it is only the needle that will settle the question. As far as I know, no patient has been permanently hurt by having a needle put in the chest when there was no pus there. On the other hand, failure to put a needle in the lung may make a serious difference to the patient. When a patient has a persistent elevation of temperature, persistent elevation of white count, persistent elevation of pulse or any one of these, empyema must be suspected, whether or not there are physical signs.

Meeting of the Medical Society of the County of Monroe, New York

DR E G WHIPPLE, Rochester, N Y. About two years ago the Medical Society of the State of New York, the State Department of Health, and associated with them the Metropolitan Life Insurance Company started an attempt in New York State to lessen the morbidity and mortality from pneumonia. This central group asked each county society to form a local committee. Our local committee has attempted two things. One was to see that information is constantly kept before the medical profession and that such information as is deemed advisable is given to the public.

It is my pleasure and privilege to present Dr Jesse G M Bullowa of New York, clinical professor of medicine at New York University and visiting physician at Harlem Hospital.

The Management of the Pneumonias

DR JESSE G M BULLOWA, New York. I shall give especial emphasis to the specific treatment of the pneumonias with the various serums that are available, to the diagnosis of pneumonia, and to some of the complications.

Most of the primary pneumonias of adults, probably 85 per cent, are due to pneumococci. Probably half of the primary pneumonias of children are due to pneumococci. It should not be forgotten, however, that some of the secondary pneumonias—the pneumonias of children ill with the infectious diseases—are due to pneumococci. Probably one in eight or ten children who develop pneumonia after measles or pertussis has a pneumococcal pneumonia. At the Willard Parker Hospital we had a child with pertussis pneumonia. We found that he had pneumococcal pneumonia, type V, he received serum and recovered. We have had many similar cases. We must make the diagnosis of pneumonia on the clinical evidences, on the history, and on presumptive signs. In pneumonia a history of a common cold which has lasted one or more days precedes the chill or pain in the side of the chest in about 70 per cent of the cases. Then there is a cough—a cough which may or may not be productive.

The diagnosis of pneumonia is often a very simple matter, but often enough it is a matter which requires considerable skill and every possible laboratory aid, including x-ray examinations, blood cultures and other examinations to eliminate other conditions. About one fourth of the cases of coronary occlusion that come to Harlem Hospital come first to my service because a diagnosis of pneumonia has been made.

I hope that the day will come when the diagnosis of pneumonia will be qualified by its etiologic agent, obtained either ante mortem or, if necessary, post mortem, and when that day comes, the physician will have to explain pneumonia deaths just the same as operative deaths.

The whole diagnosis of the type of the pneumococcus which is involved in a pneumococcal pneumonia depends on the capsule swelling—the swelling of the capsule when the organism is brought into contact with specific antiserum. At Harlem Hospital we have abandoned all other methods of typing pneumococci, not because they are difficult to do or because we have not believed in them, because we developed the slide agglutination test in our laboratories, but because we find them no longer necessary. We do a direct sputum examination or examination of the discharges that contain pneumococci. It may not be feasible to spend a sufficient amount of time searching large quantities of sputum for a single pneumococcus, so that we always employ where necessary the mouse inoculation method. The peritoneum of the mouse is a selective culture medium for pneumococci. Not only do the pneumococci grow there and the other organisms die off or are inhibited, the pneumococci in the blood stream of the mouse cause a septicemia.

There are about thirty-two different types of pneumococci. When a report is received that the organism does not belong in any of the types, or when it is type IV (unless it is IV Hooper) or group X, doubt should temporarily be cast on such a report, because the chances are overwhelmingly great that another specimen or more careful study of the same specimen will reveal a pneumococcus of definite type. In 1928-1929 we had 34 per cent of our cases that were not typed. In 1933-1934 we had only six cases, or 1.2 per cent of the cases that were studied at Harlem Hospital in adult patients, and about the same number of children that were not typed. That experience has lasted from 1934-1935, 1935-1936 and 1936-1937, so that I think that it can be said with some definiteness that practically 98 per cent of the pneumococcal pneumonias are due, at least in our community, to pneumococci of specific type for which a typing serum is available. It is true that there are a few additional types which have been recognized, and some of them have been given numbers and some may be substituted for other numbers, like XXVI, a type which is now in dispute, and also XXX. But most patients will suffer from pneumococci which can be given a number.

There is quite a difference in the prognosis in the different types not only in the prognosis there is also a great difference in the treatment because pneumococcus type I pneumonia is benefited by pneumococcus type I serum, and pneumococcus type II pneumonia is benefited only by serum which is appropriate to that type. Pneumococcus type I invades the blood stream in about one fourth of the cases, while pneumococcus type II invades the blood stream more frequently. In the bacteremic cases of the various types the death rate is almost always high, whereas in the nonbacteremic cases it is almost always low. That demonstrates the importance of knowing not only the type of case that is involved but also whether there is a bacteremia or not. It has been my experience that the blood stream is invaded usually in pneumonia of types I and II on the fourth day or later, and it may be invaded quite late in the disease.

Every year we have probably twenty cases admitted to the tuberculosis service at our hospital which are subsequently transferred to us as cases of pneumonia. We have cases that are admitted to us as pneumonia that we transfer to tuberculosis. Sometimes we have both organisms present.

A fall in the pulse rate is the most important single point in judging whether one has given enough serum. Giving too little serum is wasteful of life and of serum because, unless the patient's life is saved all the serum given is wasted. Serum treatment should not be judged by whether a patient has received serum or not. A patient who does not receive a very intense very concentrated ample amount of serum—a sufficient amount so that all the germs are exterminated and can be engulfed by leukocytes—cannot get well.

I want to emphasize the importance of the common statement in the literature that serum does not do anything in the first three days of the disease.

It takes time to treat a patient with pneumonia. It may take six or eight hours, but then treatment is done, as a rule, and the rest of the treatment is relatively simple.

One objection to serum has been that it is expensive. That is a very specious objection. The average cost of serum for a patient with pneumococcus type I pneumonia is probably \$35. The longer one waits, the more it is going to cost and the longer one hesitates about giving serum the longer the illness is going to be, the more money will have to be spent for hospital days care or for special nurses, and one may not have the patient in the end.

The most common type in most communities is pneumococcus I. Next in order are types III, II, VIII, V and VII. We have good serums for types I, II, VIII, V, VII, IV, IX, XVIII, VI, XIX and XII. We also have a serum for type XVII. We had a serum for type XX but it is exhausted but we shall have another supply. If we confined ourselves only to the four most prevalent types for which we have serum we would be able to treat 70 per cent of the pneumococcal pneumonias encountered.

I want to emphasize again that one cannot compare pneumonias as a group; one must compare them only as type.

We had fifty-four patients who were treated with serum in the first four days, and the mortality was 20 per cent. Sixteen patients treated were bacteremic, and only seven of these died or a mortality of a little over 40 per cent. The ratio of the difference between the serum and the non serum cases is 2.6. Now 2.6, when comparable populations are compared and the total numbers included are over 30 means that there are about 970 chances out of 1,000 that there is a significant difference and that the difference in the results is due to the difference in the populations. When we took the first four days serum treatment and compared it with the sixty-two cases treated on the fifth day or later, we found that the ratio of the difference to the error in the early treated cases to the late treated cases is 2.2. It is frequently said that treatment of pneumococcus type II pneumonia is of doubtful value, but I think that after this demonstration, it cannot be said of cases treated before the fifth day. Pneumococcus type II pneumonia requires a great deal more intensive treatment than other types. It requires probably twice as much serum. It requires early treatment.

Of 133 patients with type I pneumonia treated in the first four days, 6 per cent died, sixteen patients were bacteremic and 18 per cent died. After five days there were 190 patients with 89 per cent deaths, there were thirty-four bacteremic patients, with 29 per cent deaths. The ratio of the difference to the error is 1.5, which is not significant. It is never too late to give serum.

With proper precautions the incidence of anaphylactic deaths from serum is about one in 500. Without serum, in pneumococcus type I pneumonia the death rate is one in five. Good refined serum is less apt to give a reaction than crude serum. A good history should be taken. A test for sensitivity should be used—the ophthalmic test or the intradermal test. And it is very important to wait at least twenty minutes before reading the results. For rabbit serum we use an intravenous test. We inject very slowly 0.1 cc of the rabbit serum diluted with 10 or 20 cc of saline solution, and if there is no fall of blood pressure, or not more than 20 mm, we do not hesitate to go ahead and give the serum. I do not believe that one can desensitize a patient if the patient is sensitive to serum, but that does not mean that the patient should not get serum. If one doesn't give serum one may lose the patient anyhow. I do believe one can give serum by inducing a refractory state by giving epinephrine, 5 cc and then waiting at least eight minutes and then slowly injecting the serum. We inject it into the tube of an infusion set and while the patient is in an anaphylactic state.

I should like to mention briefly the adjuvants in the treatment of these pneumonias. I have already mentioned oxygen in my talk at the Pneumonia Institute. If the patient cannot be relieved of his anoxemia, he may not survive to be cured by the serum. Another thing is food. We give our patients a full diet during pneumonias. One never can tell how long a patient with pneumonia will last. He may have more hours of elevated temperature than a patient with typhoid. A very important thing is the retention of tissue fluids.

find that the giving of salt, the giving of infusions to prevent dehydration, the prevention of salt loss, or its replacement if there has been a salt loss, are of vital importance. The best way is to give a 10 per cent solution of sodium chloride, perhaps 30 or 60 cc, and restore the salt without increasing the heat. Few of our patients die as the result of dehydration, and there are a few who die of pulmonary edema. Those are the two main causes of death.

How do we treat pulmonary edema? There are several things. First we want to extract from the lung as much fluid as possible into the circulation, and we do that by injecting 50 per cent sucrose solution, which stays in the circulation for a longer time than dextrose. We use 100 cc and we may have to repeat that amount. Another thing that happens in pulmonary edema is that the antrums leading into the alveoli may be filled with bubbles of fluid, which keeps the oxygen away from the blood capillaries. We feel pretty certain that we can break through these capillaries by giving the oxygen in a pressure of 10 mm of water. We do that with a closed system of oxygen and use a rapid flow of oxygen, probably 15 cc, and measure the amount of pressure in a manometer.

DISCUSSION

DR WILLIAM S. McCANN, Rochester, N. Y. The thing that impressed me most was the way in which Dr. Bullowa follows through—checking up on the adequacy of serum administration. When he had evidence of the adequate administration of a certain type specific serum, and still something seemed to be going wrong with the patient, he investigated the possibility that other types of pneumococci were involved. The whole system by which he has checked himself up is most impressive. I think every one is grateful to him for the point on the importance of the dropping pulse. One thing I missed was a discussion with regard to the frequency and the circumstances under which aspiration from the lung is used.

DR D. B. JEWETT, Rochester, N. Y. I think I must belong to that era previous to 1934. We analyzed our pneumonia cases in the Genesee Hospital within the last year, and our mortality for all type I cases, 150 or 160 cases, was 16 per cent. That is a pretty bad mortality compared with a mortality of 2 or 3 or 5 per cent. I think the secret is that we haven't used serum in adequate amounts and at frequent enough intervals. I presume our percentage of 16 is rather general, but it is obvious that it is not at all the ideal rate.

DR G. P. BERRY, Rochester, N. Y. It seems to me that pneumonia is as much a hospital problem as diabetes. It requires continual following of the patient, laboratory studies, continuous service in the ward. The first hours are the important ones.

DR P. H. GARVEY, Rochester, N. Y. I think Dr. McCann asked Dr. Bullowa the one point I was interested in. We have difficulty in a number of cases in getting sputum early or getting positive blood cultures early. I wonder how long they wait before they do a lung puncture on a patient to obtain positive evidence of a specific type.

DR E. B. SONLE, Rochester, N. Y. I want to ask whether Dr. Bullowa at the Harlem Hospital ever does a urine typing any more. Sometimes we used to have to do that when we couldn't get sputum and before we tried taking lung punctures.

DR P. W. BEAVER, Rochester, N. Y. Referring to the use of rabbit serum, how much rabbit serum is displacing horse serum as a means of treatment?

DR B. J. SLATER, Rochester, N. Y. Would it be possible in this city in the various hospitals to set up certain standard procedures which should be followed in all cases of pneumonia, for example, taking blood cultures so that when a patient is brought into a hospital he would be assured that he would come under the advantage of a system such as Dr. Bullowa has in New York. Dr. Bullowa's lecture was very illuminating and enlightening to me.

DR JOSEPH ROBY, Rochester, N. Y. I should like to ask Dr. Bullowa a question. If one can get the same amount of concentrated serum that we used to give of the old serum, I am wondering about giving 125,000 units at the first dose. Does Dr. Bullowa think that that would be a more dangerous procedure

than giving it every two hours? I will confess that I am much more familiar with the old serum and perhaps have no right to ask that question.

DR E. G. WHIFFLE, Rochester, N. Y. Dr. Bullowa, will you kindly close the discussion?

DR J. G. M. BULLOWA, New York. We did about 2,500 lung suction at the Harlem Hospital. I have published the mortalities in my recently published "Management of Pneumonias." We did that, of course, to determine the reliability of the typed sputum. We know that in 7 per cent of the cases the type obtained from the sputum may not be the type actually causing the disease. In skilful hands—and I train my interns to do it skilfully—we have seen no harm come from it. We have sometimes seen harm come from it in the hands of an intern who was not well trained. Occasionally, if we do it late in the disease, we get a dislodgment of an embolus. Occasionally we get some bleeding, and that may do harm. The thing should be done quickly. If one dallies over it, one is bound to have the patient breathe, and then the needle will cut the lung. It is not necessary in every case. One can turn the patient on his side with the involved side uppermost, have him stay there a short time, and secretion will usually come down into the bronchus and be coughed up. It may not be much sputum, but a tiny fleck can be obtained. As a routine we use laryngoscopy, making the patient cough, having the patient cough against a swab and thus collecting a tiny fleck of mucus. Then we incubate the swab in broth for three hours and then inject the broth into a mouse. We don't use urine typing. If there is sufficient antibody in the urine, the patient is terribly ill and one can probably get it out of the sputum or blood. Testing urine is not easy. Only about 10 per cent of the series showed a positive urine. Those were very sick patients and it was not necessary to use that method.

DR BEAVER asked about rabbit serum. Nobody can tell whether rabbit serum will displace horse serum. The reasons for trying rabbit serum are, first, patients may be sensitive to horse serum; secondly, it is probable that the rabbit serum does, as Goodrich suggests, penetrate farther than horse serum. There are also commercial reasons—it requires a much smaller investment of capital.

Those of us who are working with horse serum will have to work with the manufacturers until they can produce a serum which is concentrated, which should have about 4,000 to 5,000 units per cubic centimeter, which should be possible to give in large doses without giving acetylsalicylic acid first. With the processed rabbit serums we have given about 200 cc and even more at a single injection, preceding the injection with acetylsalicylic acid so as to have the patient in a refractory state. The reason we do not give the horse serum in a large single dose, which is the ideal way, is that we think the chill is distinctly harmful. We do not like to give serum to a patient who has a high temperature, so we frequently lower these high temperatures first so as to have a margin of safety. When the temperature is down to 102, we continue to give the serum. The reactions usually come about one hour or an hour and a half after the injection, so we set the two hour interval so that if there is a reaction we shall not give additional serum. Why some serums can be given in doses of 2 cc or 10, 25 or even 40, without the chill, and others cause a chill with 0.5 cc I don't know. It is that problem with which we are most concerned at the present time—to get a serum that won't give a chill when given in a dose of 125,000 or 200,000 units. We want to be able to give it without giving acetylsalicylic acid.

Answering the question Dr. Slater raised about standard procedure, one of the most difficult things about my pneumonia service is the preservation of the skills that I require. When I lose my interns I have to start all over again. That is probably one of the troubles in most hospitals. Unless there is one man who can plan for a long time in running a pneumonia service—I have planned sometimes for two or three years ahead how I am going to get serum and other things for my service and then I have to educate my interns—unless there is one man in each place who will preserve the skills and keep the interns instructed, one will find it difficult to duplicate what we have been doing in New York. Unless each man is willing himself to plan ahead it would be very difficult to acquire these skills and train the interns.

SUPER FISCHERTHERM (6 METER) ACCEPTABLE

Manufacturer The Fischer Corporation, 673 Ivy Street,
Glendale, Calif

The Super Fischertherm Short Wave Diathermy Unit (Model 114-A) is recommended for medical and surgical use in the office or the hospital. It is housed in a walnut cabinet with vertical bakelite panel, there are aluminum ventilators in the top and back and wood ones in the sides. The chassis is of pressed steel. The subpanel is of wood with a galvanized iron shield on the lower side, high frequency insulation is porcelain, including tube sockets and coil supports. A large drawer occupies the lower part of the cabinet. The unit weighs approximately 180 pounds and is 39½ inches high by 31½ inches wide by 21½ inches deep. Standard equipment includes inductance cable, cuff and pad electrodes and surgical accessories for coagulation, desiccation and cutting purposes. Air spaced electrodes and supporting arms are optional.

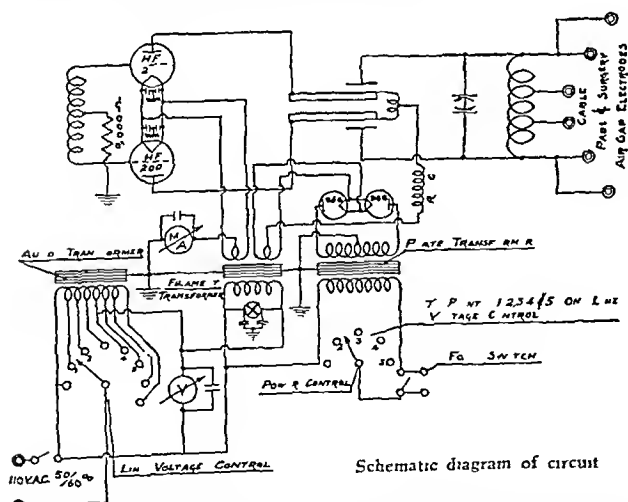

Super Fischertherm
(Model 114 A)

The circuit consists of two vacuum power tubes and two rectifier tubes in a simple arrangement. The output circuit is tuned by a split stator condenser. In adjusting for line voltage, an ohmite tap switch and a variable condenser resonance control are used.

The power input is approximately 1,300 watts. Since no reliable method for determining output power has been established, this value is not stated. The transformer temperature rise and the temperature rise at different levels within the cabinet were within the limits of safety prescribed by the Council. Burns may occur with this unit but are less likely than with conventional diathermy and may be avoided by the use of ordinary precautions.

A filter to prevent feed-back of radio frequency current into the power line is included in the equipment.

Schematic diagram of circuit

The firm submitted tests performed by a reliable investigator with regard to the heating ability of the unit when applied to the living human thigh. Eight tests were made with each of these techniques: air spaced disks, cuffs and inductance cable. Four healthy male medical students were used for the observations. Experiments were conducted on the left and right thighs alternately. Temperature measurements were made with thermocouples inserted into the anterior portion of the thigh

at depths of one-eighth inch, three-fourths inch and 2 inches or on the bone as measured from the skin straight in. The averages for the eight observations with each technique are given as follows:

Averages of eight observations, air-spaced disks

	Deep Muscle	Subcutaneous	Skin	Oral
Initial	100.2	99.2	96.0	98.8
Final	101.4	101.5	98.0	99.1

Averages of eight observations, cuff technique

	Deep Muscle	Subcutaneous	Skin	Oral
Initial	99.5	98.3	93.7	98.5
Final	102.8	103.3	100.3	99.1

Averages of eight observations, inductance cable technique

	Deep Muscle	Subcutaneous	Skin	Oral
Initial	99.6	98.6	93.7	98.7
Final	101.8	103.4	100.1	99.0

In applying the inductive cable, approximately 1 inch of bath towel was wrapped round the thigh and it was held in place by approximately four wraps of inductive cable. The position of the air-spaced electrodes was measured from the surface of the pads to the patient, from 2¼ to 3 inches. In addition to the spacing there is from one-sixteenth to one-eighth inch of rubber covering on the disk. The spacing of the two electrodes was made the same. The resulting temperature rises are higher than those achieved with a conventional diathermy tested at the same time.

The unit was tried out in a clinic acceptable to the Council and performed satisfactorily.

In view of the foregoing report, the Council voted to include the Super Fischertherm in its list of accepted devices.

REPORT
PAUL NICHOLAS LEECH, Secretary

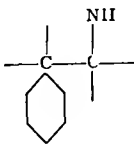

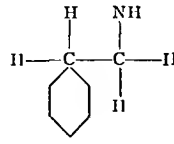

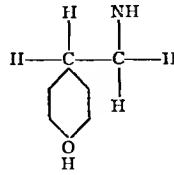

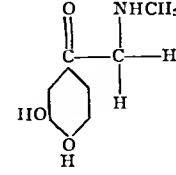

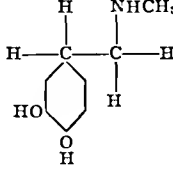

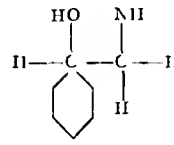

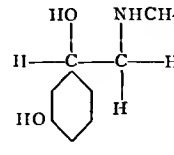

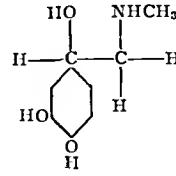

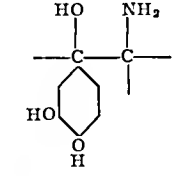

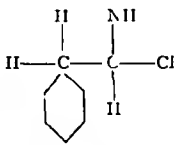

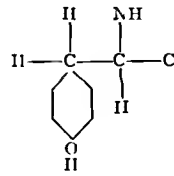

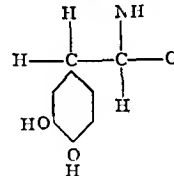

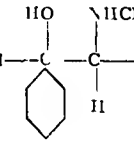

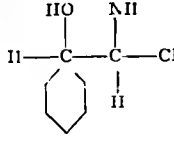

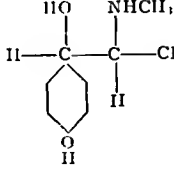

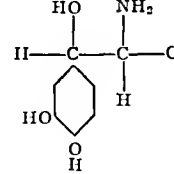

PRESENT STATUS OF BENZEDRINE SULFATE

The manufacturers of Benzedrine (Smith, Kline and French) have presented Benzedrine Sulfate and propose its use in various pathologic and substandard conditions of the central nervous system. Benzedrine, which stands accepted for New and Not Official Remedies, is the base, which readily changes to the carbonate on exposure to air (both are volatile) and is used by inhalation, whereas the sulfate is given orally. Review of the older as well as the newer pharmacologic and clinical data was required because of the great variety of conditions in which the sulfate was claimed to be useful.

EARLY PHARMACOLOGY

The experimental work with this drug consisted for the most part of the studies of the closely related phenylethanolamine (benzedrine is beta phenylisopropylamine) (see accompanying chart) and consideration must be given to this work. Allen¹ noted that Barger and Dale² had concluded that "the optimum carbon skeleton for sympathomimetic activity consists of a benzene ring with a side chain of two carbon atoms, the terminal one bearing the amino group" and that "another optimum condition is the presence of two phenolic hydroxyls in the 3,4 position relative to the side chain, when these are present an alcohol hydroxyl still further intensifies the activity." Chen and Meek³ found that tyramine and ephedrine had comparable physiologic activity, and that the work of Tainter

BENZEORINE AND RELATED COMPOUNDS

NOTE: This chart indicates the chemical but not the stereochemical relationship of the e compounds. *Kephrene* is included with the ethanes from which it differs only in that an oxygen replaces two hydrogens on the α carbon. A correct chemical name for the compound is 3,4 dihydroxy benzyl methylamino methane. *Synephrin* is not included but differs from *Neosynephrin* in having the phenolic hydroxy in the 4 instead of in the 3 position. *Benzeldrine*, *Ephedrine*, *Epinephrine*, *Kephrene*, *Neosynephrin* and *Propadrine* are Council accepted either in the form of the base and/or of a salt of the base.

and Churg,¹ and of De Eads and Butt² indicated that tyramine and ephedrine raise the blood pressure by a different mechanism than that of epinephrine.

Alles³ studied the structure of ephedrine on the basis of the Barger and Dale⁴ configuration and the work of Schultz⁵ and Tiffeneau.⁶ He noted that it would be deduced that ephedrine

would be less active than phenylethylamine but that actually the latter is considered to have one-fifth the activity of tyramine, which in turn is considered to be equivalent to ephedrine in circulatory effect. He believed that the discrepancy was at least partially due to the differences in the drugs' initial and final effects as demonstrated by Chen.⁸ Alles³ then undertook his study of phenylethanolamine.⁹ He found that it had a greater blood pressure effect in rabbits than phenylethylamine (initial effect greater and final effect comparable, resembling

first epinephrine and then ephedrine), while its toxicity (subcutaneously in guinea-pigs) was found to be one-third that of ephedrine and one-fourth that of beta-phenylethanolamine. Tainter¹⁰ also studied the pharmacology of phenylethanolamine and concluded that it resembled tyramine and ephedrine more than epinephrine.

Miller and Piness¹¹ studied phenylethanolamine sulfate and concluded that it was comparable to ephedrine pharmacologically and was considerably less toxic. It was found to be inactive orally and to have an advantageously weak pressor effect but a disappointingly weak bronchodilator effect on injection.

Later Piness, Miller and Alles¹² studied the three related compounds—phenylethylamine, phenylmethylamine and phenylisopropylamine (benzedrine). Testing the substances on dogs, they found the latter to be the only one which caused a marked rise in blood pressure which lasted for over three hours.

Tainter¹³ believed that benzedrine would eventually prove superior to epinephrine and ephedrine and it is interesting to note that even at this time Alles¹⁴ pointed out that Tainter and Hanzlik (unpublished) had completed some work that indicated that the action of these compounds was more complicated than previously suspected.

Four isomeric phenylpropylamines were studied by Hartung and Munch¹⁵ in their series on amino alcohols. They noted that Chen, Wu and Henriksen¹⁶ and Piness, Miller and Alles¹² attributed the oral efficacy of ephedrine to the presence of the third carbon on the side chain and in accordance found the phenylpropanolamine was active by mouth, whereas phenylethanolamine was not. They concluded that the optimum skeleton for pressor compounds was beta-phenylethylamine, that a shift in the relative position of the phenyl and amino groups very greatly decreases pressor activity, that substitution of a methyl on either of the two carbons in the side chain of this skeleton confers oral activity, and that the presence of the secondary alcoholic hydroxyl in phenylpropylamine serves to decrease the toxicity to a degree that becomes significant therapeutically.

Tainter¹⁷ believed that the optimum configuration of molecules for pressor activity consists of the location of the amino and phenyl groups on adjacent carbon atoms and that the phenyl group must be on a terminal carbon. It is apparent that there is general agreement on the configuration which results in the pressor effects when these chemicals, including Benzedrine Sulfate, are administered orally.

RHINOLOGY

Miller and Piness¹¹ suggested that the greatest usefulness of phenylethanolamine would be in topical application to the nose. In the same issue of THE JOURNAL the Council published a brief statement¹⁸ noting that confirmatory reports were necessary before acceptance would be in order. Piness, Miller and Alles¹² tested it and benzedrine by mouth and subcutaneously in animals. They attributed the duration of the effect as well as the oral effect to the side chain methyl group.

Bertolet¹⁹ found benzedrine useful in 122 cases of nasal congestion. He did not refer to the previous work of Hartung and Munch¹⁵ and Piness, Miller and Alles¹². However, neither of them had used this drug by inhalation and Bertolet appears to have been the first to use it in this manner. It was supplied to him in a suitable device by the manufacturer. He considered it an advantageous addition to rhinologic materia

medica because it was safe, portable and an effective measure for use between office treatments. He believed that the contra-indications were negligible but that it should be used only as prescribed by, and under the direction of, the physician.

COUNCIL ACCEPTANCE

At this time the Council declared benzedrine accepted for inclusion in New and Nonofficial Remedies²⁰ as a vasoconstrictor for local application and inhalation in rhinology.

Following the publication of the Council report Byrne²¹ reported the use of benzedrine in the treatment of fifty or more cases of various types of rhinitis. In the vasomotor type he found that the amount of secretion was diminished, the itching and feeling of fullness relieved and decongestion accomplished. His results in cases of sinusitis were poor—the drug even aggravated the condition in some cases. He felt that care should be taken in prescribing it.

Wood²² used the drug in the treatment of diseases of the eustachian tube and the middle ear. He attached a pressure line and a nasal catheter to the benzedrine inhaler and described the advantage of vapor over liquids used in a similar manner for the treatment of these conditions.

Scarano²³ compared the rapidity of shrinkage and reactions following local application of ephedrine and benzedrine. He encountered no appreciable difference in shrinking effect and did not encounter burning, lacrimation and sneezing nearly as much with benzedrine as with ephedrine. Secondary reactions such as returgescence, atony and boggy nose were less severe and less frequent with benzedrine. The drug has enjoyed wide spread use and seems to be an effective, convenient agent for the purposes for which it was accepted, provided precautions are taken to avoid overdosage as recommended in New and Nonofficial Remedies and on the labels.

BENZEDRINE SULFATE

The sulfate, however, is recommended for oral use in a variety of clinical conditions. The Council is fully aware of the widespread publicity which has followed in the wake of the launching of this new form of benzedrine. Attention was called to certain abuses editorially in THE JOURNAL²⁴ as well as in the *British Medical Journal*²⁵ and the *Pharmaceutical Journal*. Apparently the firm has some qualms about the rather extensive use of the drug and has mailed to many physicians a letter which suggested some caution in its use.

The extensiveness of the claimed uses in this letter, as well as those suggested in the lay press, demands a rather thorough consideration of the pharmacologic and clinical studies which have been reported since the Council acceptance of benzedrine. The A. M. A. Chemical Laboratory has examined this brand of benzedrine sulfate and found it to be satisfactory.

LATER PHARMACOLOGY

The pharmacology of phenylisopropylamine was studied rather extensively by Detrick, Millikan, Modern and Thunes. They mentioned the early work of Hartung and Munch¹⁵ and noted that Pedden, Tainter and Cameron²⁶ and Cameron and Tainter²⁹ confirmed the actions of this drug on dogs.

described by Alles³⁰ and Alles and Prinzmetal³¹. They referred to their own previous studies (Patek and Thienes³² and Thienes³³) and continued the study of the effects of this drug in dogs, cats and rabbits. Their study consisted principally of effects of combinations of benzedrine with other drugs. They believed that benzedrine was proved to be a central nervous system stimulant in anesthetized animals because of the increase in rate and depth of respirations, as well as the struggling and vocalizations observed in their experimental animals. They described a pressor action in all the animals and noted that tachyphylaxis was marked. It was observed that the pressor effect was moderately decreased by cocaine and ergotamine. In low concentrations (10⁻⁶ or less) benzedrine salts had no effect on excised smooth muscle of rabbits or guinea-pigs and inhibited the intestine of the cat. In high concentrations (10⁻⁴ or higher) benzedrine caused contraction of all smooth muscle, although a temporary inhibition of cat ileum and duodenum preceded the contraction produced by the benzedrine. This inhibition was prevented by atropine and decreased by nicotine, while the contraction itself was not altered by atropine but was decreased by nicotine. No effect of atropine or nicotine was noted in the responses of rabbit tissues to benzedrine but the contraction of the guinea-pig intestine was abolished by atropine. Ergotamine abolished epinephrine action on cat duodenum but merely decreased the action of benzedrine. Hydrastine decreased or abolished the actions of epinephrine and of benzedrine while yohimbine contracted the intestine but caused negligible alteration of the actions of epinephrine and benzedrine.

Myerson, Loman and Dameshek³⁴ studied the hematologic properties of benzedrine sulfate and claimed an increase (following the oral administration of therapeutic doses) in red blood cell counts of 1½ to 3 million with doubling, tripling and quadrupling of the leukocyte counts. Recently Simpson³⁵ has attributed this as with other vasoconstrictors to "the extrusion into the circulation" of these cells "from the storage and hematopoietic centers, including the bone marrow." There was no increase in hemoglobin or immature white cells (except for an occasional increase in neutrophils). Myerson and his associates³¹ also studied the basal metabolic rate and found no change following its use. Lagen, Solev and Leake³⁶ however, found individual variations which indicate that further study is necessary before it can be said that the drug is without effect on the rate. Peoples and Guttmann³⁷ did not find any change in the blood sugar levels following the clinical use of this drug. Myerson and his associates³⁴ also studied the blood sugar levels. They did not encounter change in the size of the pupil or symptomatic change in the gastro-intestinal, respiratory or genito urinary functions.

Pressor Effects—Alles³⁰ found that benzedrine was equal in pressor effect to beta phenylethylamine when injected intravenously in dogs under barbitol anesthesia and that it had a much weaker but longer effect than epinephrine. Similar results were obtained with 4 hydroxy- and 3,4 dihydroxy-phenylisopropylamine (4 hydroxy- and 3,4 dihydroxy α -phenyl β amino propane—see chart) and phenylethylamine. The most prolonged effect and the nearest to epinephrine in initial effect was produced by 3,4 dihydroxy phenylisopropylamine. The propylamines were found to be much more toxic than the ethylamines but this toxicity was lessened by the introduction of the

hydroxy groups to the compounds. Nathanson³⁸ has experimented with 4 hydroxy phenyl isopropylamine (supplied by the makers of benzedrine) and found it effective in the prevention of cardiac arrest without central nervous stimulation or unpleasant side effects.

Tainter¹⁷ made a very extensive examination of forty-four sympathomimetic amines. He noted that Piness, Miller and Alles¹² and later Alles³⁰ reported that benzedrine maintained blood pressure at a high level after subcutaneous or oral administration in man and that Hartung and Munch¹⁵ had obtained comparable effects in dogs by injection. Tainter¹⁷ considered the pressor activity of benzedrine high and regular enough to attempt the determination of the possible mechanism. However, he found that he could not employ the usual procedures because the second injection of the drug caused a fall of blood pressure. He avoided this effect by injection of cocaine or ergotamine before administration and then compared responses with those of the controls. He determined that when the epinephrine response was doubled by cocaine the pressor response to this propylamine was abolished and that when the epinephrine response was reversed by ergotamine this compound still gave a good rise of blood pressure.

Many of those who have studied benzedrine clinically have noted its pressor effects. In this connection it is necessary to consider some of the symptomatic and pressor effects of epinephrine. Loman and Myerson³⁰ noted that epinephrine causes a rise in the intracranial pressure together with a rise of arterial and internal jugular venous pressures and attributed the former to the arterial rise, since there was a vasoconstriction of the cerebral blood vessels. Gibbs, Gibbs and Lennox⁴⁰ noted that the cutaneous injection of amounts of epinephrine sufficient to cause a marked rise in blood pressure caused a great increase in cerebral blood flow, this increase undoubtedly being secondary to increase in blood pressure. Minute amounts of epinephrine caused a slight rise in flow without change (or with a fall) in blood pressure suggesting a vasodilator action. Sulman⁴¹ claimed similar pressor and depressor responses in his clinical studies of the inhalation of benzedrine. Anderson and Scott⁴² reported both increases and decreases in pulse rate and blood pressure in a series of six cases. Myerson and his associates⁴³ observed the pressor effects of benzedrine given orally, subcutaneously and intravenously in a special but unusually well controlled series of cases. Most of them were "passive unemotional cases of dementia praecox who lay perfectly quiet throughout the entire procedure." In eighteen cases from 9 to 50 mg of the drug was administered subcutaneously and resulted in gradual rises of from 10 to 54 mm of mercury—reaching a maximum in from eleven to eighty-five minutes and returning to normal in from one and one-half to eight hours. During this period the pulse rate was diminished from 4 to 25 beats per minute in twelve cases unchanged in four and increased in two. Fourteen patients were then given 40 mg of benzedrine sulfate by mouth and registered increases of from 8 to 68 mm of mercury in systolic pressure. The effect was slower than with the subcutaneous administration and the pulse rate was more consistently lowered. The authors administered from 20 to 40 mg subcutaneously, followed it with from 20 to 30 mg of acetyl-beta-methyl choline and the effect of the benzedrine was more than counteracted for the period of activity of the choline (from ten to twenty minutes), after which the effects of benzedrine supervened. Further experiments indicated that atropine enhanced the pressor effect of

benzedrine and that amital counteracted the pressor effect when given either before or after the benzedrine. Peoples and Guttman³⁷ described increases of systolic pressures lasting from two to four and occasionally to twenty-four hours. This increase was found to be greatest in those with hypotension and there was generally an increase in pulse rate which lasted longer than the blood pressure rise. That clinical results are dependent on this effect is apparently disputed by the finding that pressor effects occurred without results and therapeutic results occurred without pressor effects. However, it has been suggested that there is a definite relationship, although it is not apparent in every case. Guttman⁴⁴ noted that the drug was suitable for experimental alterations of blood pressure because its pressor effect was between that of epinephrine and ephedrine as to the rapidity and intensity of action.

NARCOLEPSY

Uhlrich, Trapp and Vidgoff⁴⁰ discussed the use of the drug in narcolepsy and noted the many varied but unproved theories of the etiology of this condition. It is usually considered to be chronic and incurable, but spontaneous recovery without treatment has been reported. Remedies which have been used to relieve the condition include psychotherapy, endocrine medication (thyroid, pituitary) and caffeine⁴¹. The only remedy which has proved successful to any appreciable degree was ephedrine sulfate, which was first used by Janota⁴².

Uhlrich and his co-workers⁴⁰ encountered sleeplessness in a patient given benzedrine inhalations and experimented with it in cases of narcolepsy without success. It was not until Prinzmetal and Bloomberg⁴³ published their report of its oral use in this condition that they reinstituted their study. Prinzmetal and Bloomberg⁴³ studied nine cases of narcolepsy, in which complete relief from attacks of sleep and practically complete relief from cataplexy was obtained. They considered it three times as effective as ephedrine in preventing attacks of sleep and noted its efficacy in cases that did not respond at all to ephedrine. A footnote referred to four other successful but less carefully studied cases. The authors did not consider the possible pressor effects of the drug.

Uhlrich and his co-workers⁴⁰ used it orally in six cases with consistently good results. They suggested that the difference between the oral and inhalation effects of this drug might be largely a matter of dosage. Peoples and Guttman³⁷ confirmed the insomnia-producing effects noted by these workers in treating cases of narcolepsy. (An additional reference to its use in narcolepsy⁴⁴ has appeared since the report was formulated.)

MENTAL EFFECTS MOOD AND FATIGUE

Peoples and Guttman³⁷ described the following effects in a group of twenty-five institutionalized patients: "feeling of confidence, elation and well being; happier, brighter, more energetic and free from care and worry." Myerson and Ritvo⁴⁹ described "a definite feeling of well being" and later Myerson⁵⁰ studied its effect on mood and fatigue in normal and neurotic persons. He described the following results, yet noted that a thorough study of the effects had not been made. Normal non-psychiatric and non-neurotic persons suffering from fatigue and light malaise due to insufficient rest received immediate benefit and relief of a pressor type. He suggested that as an emergency measure the drug was probably of benefit to normal persons. He studied it in certain cases of narcosis associated with depression, fatigue, anhedonia and many states of psychoses of this type. He stated that the ameliorating effect

was neither permanent nor curative, but he noted that it helped to combat morning apathy and depression.

Nathanson⁵¹ noted amelioration of fatigue in 80 per cent of his cases of exhaustion and lessening of migraine in four cases in which this condition was associated with attacks of weakness. He described "a sense of increased energy and capacity for work" in more than half the cases. In addition, a feeling of exhilaration and sense of well being was a consistent effect and "patients volunteered that there had been a definite increase in mental activity and efficiency." He also described similar effects of a so-called pick me up nature in fifty-five normal individuals. It must be considered, however, that the results are purely subjective and information received by the Council indicates that this use is ill advised.

Guttman⁴⁴ noted the stimulating and euphorizing effect on normal persons with similar results in depressive patients. He described two groups—one with an initial stage of mild intoxication followed by mild elation similar to that which the second group encountered without the prodromal dizziness or giddiness. Thus he interpreted to indicate influence on the mood and on the psychomotor retardation. These effects could not be entirely correlated with the pressor effect, since they occurred even when a depressor effect ensued, but he believed there was a close relationship. Guttman⁴⁴ also suggested a possible interrelationship between the effect on mood and the effect on sleep.

GASTRO-INTESTINAL EFFECTS

Myerson and Ritvo⁴⁹ described the effect of this drug on spasm of the gastro-intestinal tract. They found that it was of value in diminishing or abolishing the spasm when due to whatever cause such as unpleasant emotion, organic disease of the gastro-intestinal tract and reflex spasm (spastic colitis and pylorospasm) due to disease elsewhere in the body. It was found that the drug facilitated x-ray study of the gastro-intestinal tract and was useful in differentiating functional and organic spasm. Later Ritvo⁵² noted that, when given orally or by injection, the drug is sympathomimetic in character and that results of its use include relaxation of the spasm of stomach, pylorus and intestine. This permits better roentgenographic study of the stomach and duodenum. The tone of the stomach is lessened, but peristalsis is diminished only slightly. The colon becomes widened, the haustrations diminish in number and depth, and spastic deformities of the bowel disappear. The patient is able to retain the opaque enema with less discomfort.

OTHER CLINICAL USES

A preliminary report of the use of benzedrine in the control of blood pressure during spinal anesthesia has been issued by the Mayo Clinic⁵³. In a series of twenty-six cases involving operation on the urinary tract, benzedrine was given by inhalation. There was a resultant mild pressor action in twenty-three cases. It was necessary to give the drug before the decrease in blood pressure became alarming because of the lag between administration and pressor effect.

Its effect on intelligence scores (Cattell test) in certain institutionalized patients has been studied by Sargent and Blackburn⁵⁴. The results show some increase in score. The author felt that the drug had more effect on those suffering from pure emotional upsets than on the schizophrenic.

DOSAGE

The dosages used in the experimental and the early clinical work were as follows:

Prinzmetal and Bloomberg⁴³ used from 10 to 40 mg. Uhlrich and his co-workers⁴⁰ from 20 to 50. Peoples and Guttman³⁷ from 10 to 80. Myerson and Ritvo⁴⁹ from 10 to 40. Myerson⁵⁰ from 5 to 20 and Pines, Miller and Alkes⁵¹ 10 mg. Nathanson⁵¹ used from 10 to 20 mg. in the morning.

the treatment of exhaustion. Subsequent evidence indicates that there is considerable variability in the response of individual patients. It is advisable, therefore, to institute treatment with from 25 mg to 10 mg and increase this dosage up to not more than 20 mg three times a day, depending on the necessity of increasing the dosage to obtain a therapeutic response.

REACTIONS AND CONTRAINDICATIONS

Doses which caused reactions were usually those which were greater than the amount necessary to produce therapeutic effects.

A correspondence item in THE JOURNAL⁴⁹ suggested that continued administration may result in a pressor effect. Sleeplessness has been encountered with the overdosage with the inhaler and the solution.

Overdosage and sometimes therapeutically effective doses of benzedrine sulfate have resulted in many reactions. Prinzmetal and Bloomberg⁴⁷ encountered insomnia, hyperexcitability (overstimulation of the central nervous system with dilated pupils and inability to relax). Uhlrich and his co-workers⁴⁸ encountered nausea, anorexia, and in one case an extramenstrual period. Myerson and Rivot⁴⁹ encountered unpleasant effects in 2 per cent of their 200 patients including chills, nausea, restlessness and diarrhea, all within several hours after administration. Myerson⁵⁰ noted the restlessness and sleeplessness resulting from the administration of the drug orally in the afternoon.

Nathanson⁵¹ described a tendency to loquaciousness. Ten patients noted a marked loss of appetite and definite reduction in weight. Occasionally secondary depression followed initial stimulation. Dryness of the mouth, disturbed sleep, transitory tremor of the hands, sweating and palpitation—usually of short duration—were noted. The drug was discontinued in three cases because of sleeplessness (in two) and severe palpitation (one). He did not encounter a rise in arterial pressure; he found no extrasystoles except in one case, four patients having extrasystoles showed no additional cardiac effect from the drug. He goes so far as to point out that the use of the drug may lead to harmful results in that patients may overdo without receiving the warning of fatigue. He also recommends administration under the physician's prescription only. He notes that complete indications and contraindications are not yet available.

Apparently there is no tolerance, as response has been found to be the same after fourteen months' use in one case and after shorter periods in other cases. Wilbur, MacLean and Allen⁵² noted that in their opinion the drug should not be used continuously unless the patient is less than 60 years of age, has no evidence of cardiovascular disease and can be closely watched. Others have suggested that cumulative effects may be deleterious. Anderson and Scott⁴² noting no record of severe cardiovascular effects produced by benzedrine reported an unusual case in which the patient went into collapse after 30 mg of benzedrine. They recommended that until more precise knowledge of the cardiologic effects of benzedrine is obtained caution should be exercised in the administration of doses of from 10 to 20 mg or more, particularly in elderly subjects.

SUMMARY

After consideration of the available evidence the Council declared that the permissible claims for the usefulness of Benzedrine Sulfate should not exceed the following stipulations:

Narcolepsy.—Benzedrine Sulfate is useful for the treatment of narcolepsy and for controlling symptoms similar to those of narcolepsy in the treatment of postencephalitic parkinsonism. Its use is not recommended in the treatment of sleepiness and fatigue in normal individuals because of the possible danger of pressor effects from continued use, the dangers of eliminating the warning signal of sleepiness in individuals who are overdoing because of the possibility of habit formation or addiction from such use and because cases of collapse have ensued when the drug has been used for this purpose.

Mental Effects: Mood and Fatigue.—Benzedrine Sulfate is useful in the treatment of certain depressive psychopathic con-

ditions. Its use is not recommended for developing a sense of increased energy or capacity for work, or a feeling of exhilaration or as a 'pick-me up' in individuals other than those under the strict supervision of the physician. The Council believes that its use for these purposes should be confined to institutions since the dangers involved in the use of the drug for this purpose in those going about their daily tasks are similar to the dangers mentioned in connection with fighting off sleep.

Gastro-Intestinal Effects.—Benzedrine Sulfate is useful in facilitating roentgenographic study of the gastro-intestinal tract but it is not recommended at present for use in the treatment of spastic colitis and pylorus spasm.

Other Clinical Uses.—Further evidence is necessary before serious consideration can be given to these various other applications of this agent to therapeutics.

Reactions and Contraindications.—The very nature of the therapeutic effects as well as side actions of this drug requires that its use be promoted with proper cautionary statements as to pressor effect, hyperexcitability, gastro-intestinal disturbance, restlessness and sleeplessness and in overdosage, chills, collapse and syncope. It should also be carefully noted that the drug is contraindicated in those having cardiovascular disease, especially when hypertension is a sequence of that disease.

Dosage.—The use of the drug should be instituted with a dose of 25 mg to 10 mg, and it is recommended that no single dose exceed 20 mg. In certain conditions it may be necessary to repeat the use of the drug two or three times daily. It is preferable, if possible, to administer the effective quantity during the morning.

CONCLUSION

The Council declared that Benzedrine Sulfate (Smith, Kline & French) and the submitted dosage form would be accepted for inclusion in N N R provided the firm agrees to limit the claims for the usefulness of the drug to the treatment of narcolepsy and postencephalitic parkinsonism, to limit the claims for its usefulness in depressive mental states to the stipulations of this report, and further, provided there are no other conflicts with the rules.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PALL NICHOLAS LEECH, Secretary

CALCIUM GLUCONATE (See New and Nonofficial Remedies 1937, p 150)

Calcium Gluconate Effervescent Flint. Each gram contains calcium gluconate U S P 0.5 Gm, citric acid 0.25 Gm, and sodium bicarbonate 0.25 Gm.

Dosage.—Orally, for adults 10 Gm (150 grains) three times a day; for children 4 Gm (60 grains) three times a day.

Manufactured by Flint, Eaton & Co., Decatur, Ill. U S patent 1,983,954. No U S trademark.

Calcium gluconate effervescent occurs as a white, coarsely granular, odorless material with a biting acid taste. Its solubility in water is not less than 28 Gm per hundred cubic centimeters at 25°C. The resulting solution is acid to litmus. The loss in weight over sulfuric acid is not greater than 0.5 per cent. The product conforms to tests for purity of calcium gluconate U S P. The calcium oxide content is not less than 6.0 per cent nor more than 6.4 per cent.

Dissolve approximately 5 Gm of calcium gluconate effervescent accurately weighed in water to make 100 cc of solution. Transfer a 25 cc portion to a 250 cc beaker, boil for two minutes and while boiling add 25 cc of a hot saturated solution of calcium hydroxide and continue boiling for five minutes. Digest on the steam bath for two hours and filter while hot through a hot Gooch crucible, wash the residue with boiling water and dry to constant weight at 100°C. The citric acid content is not less than 24.5 per cent nor more than 25.8 per cent. Dissolve approximately 10 Gm of calcium gluconate effervescent accurately weighed in water to make 100 cc of solution. Transfer a 25 cc portion to a suitable Erlenmeyer flask, boil for two minutes, cool and titrate with tenth normal sodium hydroxide using phenolphthalein as an indicator. A 1 Gm sample requires not less than 7 cc nor more than 7.6 cc of tenth normal sodium hydroxide. Transfer about 0.1 Gm of calcium gluconate effervescent accurately weighed to a 120 cc beaker and dissolve in 5 cc of distilled water, cool the beaker and contents in ice water and add 25 cc of a 15 per cent magnesium uranyl acetate solution. Place the mixture in an ice bath at 20°C and allow to stand for twenty-four hours. Filter with suction and wash with 95 per cent alcohol saturated with sodium magnesium uranyl acetate. Dry the precipitate at 110°C for thirty minutes, cool and weigh. One Gm of sodium magnesium uranyl acetate being equivalent to 0.0153 Gm of sodium, the sodium content is not less than 6.4 per cent nor more than 7.0 per cent.

SATURDAY, DECEMBER 18, 1937

ESSENTIAL AMINO ACIDS IN NUTRITION

Of the twenty-two amino acids commonly obtained by the hydrolysis of proteins, ten are now known to be essential for growth and twelve are considered nonessential. Such is the brief announcement¹ that provides the concluding chapter to a series of brilliant researches conducted at the University of Illinois for more than the last decade but having their origin earlier in the contributions of Osborne and Mendel. The latter workers showed more than twenty years ago that proteins differed in their nutritional value. Animals could not grow when restricted to a diet in which the sole source of protein was zein or gliadin, the alcohol soluble proteins of corn and wheat respectively. Zein is a peculiar protein in that it contains neither tryptophan nor lysine, and gliadin contains only small amounts of lysine. The addition of the amino acids in which each of these proteins is deficient promoted normal growth and it was concluded that tryptophan and lysine must be furnished by the diet in order that growth might occur. Evidence was also obtained to show that uronic acid, it needed by the body for growth, can be formed from other sources and therefore need not be included in the diet. Proteins accordingly could be divided into complete and incomplete proteins depending on whether they provided all the indispensable amino acids or were deficient in one or more of these. This method of study was hampered by the relatively few proteins that had been isolated in pure form and were adaptable for feeding experiments.

The next advance in the study of the nutritive value of the individual amino acids came as a result of the

...the protein in
...treated with
...essential amino
...remove the
...hydrolysis
...from which

to Acid and

are destroyed during the treatment. From the mixture of amino acids that comprise a hydrolyzed protein, groups of amino acids would be removed and other added. By this technique it was found that histidine is another amino acid which is essential for growth. The limitation to this method of procedure was the difficulty of chemically separating the amino acids.

The obvious possibility of feeding mixtures of pure amino acids remained an unattainable goal until Rose and his collaborators at the University of Illinois began an extensive program of preparing and accumulating all the known amino acids in quantities sufficient to permit feeding mixtures of them to rats. Numerous difficulties were encountered along the way but one by one they were successfully overcome. Then it was learned that the feeding of all the known amino acids, including methionine which had been discovered by Mueller in 1922, failed to promote growth. The addition to the diet of a small amount of protein insufficient in itself to promote growth, gave good results. The bold prediction was made that in proteins there must be some amino acid which at that time had not been discovered, that this unknown amino acid was indispensable for growth and that it was present in some proteins in higher concentration than in others. An intensive study was begun at once to learn the nature of the hypothetical amino acid which had eluded the attention of all other investigators in the field of protein chemistry. Various proteins were hydrolyzed and fractionated by different chemical means, and the fractions tested for their growth promoting properties when added to mixtures of amino acids, eventually, from a potent fraction, the amino acid itself was isolated. Further work led to its identification as one of the four possible alpha-amino-beta-hydroxybutyric acids. To the naturally occurring form of this indispensable amino acid its discoverers have given the name threonine.

Having thus obtained a knowledge of all the amino acids in ordinary proteins, Rose and his collaborators were able to continue their experiments with the hope of attaining a successful solution to the problem of the nutritional importance of each amino acid. When all the amino acids were fed, including threonine, good growth was obtained. Individual amino acids were omitted from this mixture and the effect on the growth of the animals was observed. The denouement of the story thus developed rapidly. The twenty-two common amino acids now can be classified precisely according to their growth effects. Among the essential amino acids are lysine, tryptophan, histidine, phenylalanine, leucine, isoleucine, threonine, methionine and valine. Arginine, which at one time was thought to be non-essential, should also be classified as an essential amino acid because the animal body cannot synthesize this substance at a rate fast enough to permit normal growth. The nonessential amino acids are alanine, acetic acid, alanine, serine, norleucine, gamma-aminobutyric acid, and aspartic acid.

glutamic acid, hydroxyglutamic acid, proline, hydroxyproline, citrulline, tyrosine and cystine. For many years cystine was thought to be an essential amino acid. Later work has made clear that the other sulfur-containing amino acid of proteins, methionine, is essential for growth but that cystine is not. However, if the amount of methionine in the diet was not sufficient to permit normal growth, it was observed that the addition of small amounts of cystine would accelerate growth. It has been suggested that methionine forms some substance which also can be formed from cystine and that this derivative is necessary in order that growth can occur. To a limited extent, therefore, cystine can replace a portion of the methionine in the diet.

This work on the nutritional significance of the amino acids has come to fruition so rapidly that it is difficult to grasp all the possibilities that the future portends. It has been suggested that a method might be developed for the study of the origin of each of the dispensable amino acids and of the chemical conversions involved in their formation. The amino acids obtained from foods are utilized by the body for the formation of the proteins of the blood and tissues and for the production of some of the hormones and other substances that contain nitrogen. The chemical changes that take place in the body are exceedingly important in health and in disease, and work of the kind reported by the Illinois investigators will lead eventually to a firmer understanding of some of the numerous transformations undergone by the important nitrogenous components of the body.

GRADUATE INSTRUCTION IN SYPHILIS CONTROL WORK

The Advisory Committee to the U. S. Public Health Service which outlined a venereal disease control program for state and local health departments¹ agreed on the importance of the postgraduate instruction of practicing physicians in the clinical management and public health control of syphilis and gonorrhea. Two types of training are to be fostered, the short review course in current diagnostic and therapeutic practice and prolonged intensive training in venereology for the specialist.

Because of the need for the assistance and cooperation of the physician in private practice with the health department, the U. S. Public Health Service has made a special attempt to provide postgraduate training for physicians in the fundamentals of the clinical management and public health control of syphilis, gonorrhea and the other venereal diseases. Special allotments of funds, appropriated under the provisions of the Social Security Act, have been made to a number of states.

Special allotments have been made to the state health officers of California, Massachusetts, New York, Ohio

and Tennessee for the development of a special postgraduate course in venereal disease control work. Under this plan the course of postgraduate training is organized by the state health officer and the authorities in the medical school that is selected. The training is intended primarily for health officers and for private physicians who cooperate with state and local departments of health. Applicants to be eligible for training must be nominated by the state health officer of the state from which they come. Except for nominal registration fees in one or two medical schools, the training is provided without charge. It is hoped that the medical schools which have been selected will serve health officers and physicians from all the states which are conveniently located in that part of the country.

More than a year ago a special course of training in syphilis control work was developed in the Johns Hopkins University School of Medicine with funds allotted by the Public Health Service to the Maryland State Department of Health. Shortly thereafter a course of training was developed through the utilization of Social Security funds by the Pennsylvania State Department of Health in cooperation with the University of Pennsylvania. The latter course is for the purpose of training physicians, public health nurses and medical social workers in case finding and case holding methods as they pertain to the control of the venereal diseases.

For the Negro physician a special allotment has been made to the District of Columbia Health Department and a course has been developed at Howard University. Negro physicians nominated by state health officers are eligible for this postgraduate training at very small cost.

The magnitude of the venereal disease problem in this country is such as to require the full cooperation of the medical profession if success is to be attained. The short review courses recently organized, in which the modern clinical management of the venereal diseases is taught, will not qualify the physician in general practice as a finished specialist. Present facilities for the training of specialists are not available to provide entirely for the care of the large number of patients infected with syphilis and gonorrhea who now require medical attention. However, there is no reason why the physician in general practice should not treat the average patient with early and latent syphilis unless special complications develop, which indicate the need for consultation with an expert. To be able to take on this new duty, however, it is essential that the general practitioner know the fundamentals of the management of syphilis and be aided by his health department. Every health officer and every physician interested in the control of syphilis and gonorrhea should see that those who diagnose and treat these diseases know the basic principles. The postgraduate courses of training that have been developed should be utilized to their fullest extent.

1. Recommendations for a Venereal Disease Control Program in State and Local Health Departments. Report of an Advisory Committee to the United States Public Health Service. Ven. Dis. Inform. 17:1 (Jan.) 1936.

THE CHANGE OF PROTEIN TO CARBOHYDRATE

Claude Bernard's discovery in 1848 of glycogen in the liver had far reaching significance. Not only had he demonstrated a "nouvelle fonction du foie" but through the experimental approach employed he opened a question of fundamental significance in intermediary metabolism, he offered convincing evidence of the transformation of protein to carbohydrate in the animal organism. Soon after the announcement of this new function of the liver, somewhat similar cogent evidence of the change of carbohydrate to fat was developed by Lawes and Gilbert. The fundamental nature of protein metabolism compelled investigators in this field to consider seriously the extent of the metabolic transformation of protein to sugar. Aminoacetic acid was shown to increase the hepatic glycogen in fasting rabbits. Studies on diabetic patients showed that some two thirds of the meat and gelatin fed appeared as urinary sugar. Later it was demonstrated that aminoacetic acid, alanine and asparagin were changed to sugar in the depancreatized dog. The subject was greatly extended by Graham Lusk, who used phlorrhizinated dogs as experimental subjects. Largely on the basis of his studies the then known amino acids were divided into the glycogenic and nonglycogenic amino acids. From the foregoing investigations as well as others employing as criteria the change in respiratory quotient and the antagonism to insulin hypoglycemia, the current view accepts aminoacetic acid, alanine, serine, aspartic acid, glutamic acid, cystine, methionine, proline and arginine as glycogenic amino acids.

Recently a renewal of interest in this question has emphasized the importance of details of chemical structure of the amino acids, a factor not heretofore appreciated. Criticizing the use of phlorrhizin as unphysiologic, Butts and his co-workers¹ have employed the effect on artificial ketosis induced in experimental animals by oral administration of sodium acetoacetate as well as the change in amount of liver glycogen brought about by optically active forms of the amino acids. It was found that aminoacetic acid, early recognized as an important glycogenic amino acid, is inferior in this respect as well as in ketolysis to both *dl*-alanine and *d*-alanine. The latter compound, the naturally occurring form of alanine, is superior to the others. As ketolytic substances *l*-aspartic acid, *d*-glutamic acid and *dl*-aspartic acid are all inferior to *dl*-alanine, whereas *l*-aspartic acid, *dl*-aspartic acid, *d*-glutamic acid and *dl*-glutamic acid are glycogenic in the order named.

Of considerable interest are the observations on the various leucines. Leucine has persistently given negative results in experiments on glycogenesis, in these more quantitative studies it is reported to yield carbon

was formed by *dl*-isoleucine and by *dl*-norleucine and the latter was also ketolytic. These observations are interesting in the light of the recent demonstration of the essential nature of leucine and isoleucine, it would appear that their indispensability does not rest primarily on the metabolism of the non nitrogenous portion of the molecule. These newer observations on the correlation between the finer details of the structure of amino acids and their metabolic change to carbohydrate emphasize again the extraordinary specificity of biologic processes. In time they may exert unsuspected influence on the conceptions and treatment in the field of internal medicine.

Current Comment

CANADIAN EXPERIENCE WITH ZINC SULFATE SPRAYS FOR PREVENTION OF POLIOMYELITIS

The serious outbreak of poliomyelitis in and around Toronto this year afforded an exceptional opportunity for the study of the prophylactic value of zinc sulfate sprays. The report by Tisdall and his co-workers¹ on this subject deserves careful study. A trial of nasal spraying was approved by the Department of Health of Ontario on August 29. It was agreed that each child should be sprayed on two occasions, ten or twelve days apart, and that from 0.5 to 1 cc of the solution should be placed in each naris in each spraying. The solution contained 1 per cent zinc sulfate, 1 per cent pontocaine and 0.5 per cent sodium chloride. The spraying was done according to the technique of Pett Echols and Richter but differed from their recommended procedure in that it was not administered on three successive days, since this method was considered impracticable. The peak of the epidemic occurred during the week ended September 4. The first spraying, begun on August 31 and completed by September 7, was performed by forty-four attending otolaryngologists of eight hospitals in the city. In the period of one week from the authorization of the study, 5,231 children had received the first spraying. The second spraying extended from the 13th to the 16th of September. No serious complications occurred. Nine hundred and nine tests, representing 740 children were made to determine the number who had lost their sense of smell. From these observations it would appear that some 25 per cent had anosmia. A representative control group of 6,300 children was obtained in the city proper. Among the 4,713 children who were sprayed twice, eleven cases of poliomyelitis occurred up to October 12, thirty days from the second spraying. One of these occurred six days after the first spraying and was not included in the analysis. In the control group of 6,300 children eighteen cases occurred. The attack rate in the period from seven days after the

first spraying to thirty days after the second spraying was 21 in the sprayed group and 29 in the control group. The difference is not statistically significant. In the total of the city and suburban groups, the attack rates were 29 in the control group and 18 in the sprayed group, which also was found not to be statistically significant. The report concludes that since the spraying method employed in this study must be conducted by otolaryngologists or other physicians especially trained in intranasal treatment, requires special facilities and cannot be done quickly enough to meet the emergency of an outbreak, it cannot be considered a practical public health procedure.

HEPATIC FUNCTION AND VITAMIN D

In 1933 Gerstenberger¹ concluded from clinical evidence that the action of antirachitic vitamin D is in some unknown way mediated through the liver. Walter Heymann² of the Babies and Children's Hospital, Cleveland, has recently attempted to confirm this conclusion by a study of the effect of experimental hepatic insufficiency on vitamin D therapy in rachitic animals. Rickets was caused and maintained in rats by means of the Steenbock rachitogenic diet. Experimental biliary cirrhosis was produced in one group of rachitic rats by double ligation and transection of the common bile duct. Severe hepatic injury was produced in other groups by intramuscular injections of carbon tetrachloride. Heymann found that from ten to twelve times the routine therapeutic dose of vitamin D was necessary to cure rickets in his biliary cirrhotic group and from two to three times the normal therapeutic dose in the carbon tetrachloride group. In further support of the Gerstenberger theory, Heymann showed that the jaundice associated with experimental hepatic cirrhosis does not impair the calcifying function of the bone. While Heymann's experimental data are susceptible of several interpretations, they do seem to show that normal liver function has an adjuvant part in vitamin D therapy.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct. 13, 1937 and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p. m. eastern standard time, 1 p. m. central standard time, 12 o'clock noon mountain standard time and 11 a. m. Pacific standard time.

The dates and topics of the broadcasts for the coming month are as follows:

Diet

December 22—Milk from Farm to Table: the production, transportation, pasteurization and home care of milk; its place in the diet, processed milks.

December 29—Dietary Fads: facts vs. fallacies in relation to prevalent false notions on diet.

¹ Gerstenberger H. J. *Monatsschr. f. Kinderh.* 56: 217, 1933.
² Heymann Walter. *Proc. Soc. Exper. Biol. & Med.* 36: 812 (June) 1937.

Contagious Diseases

January 5—Sneezes and Sniffles: cause, spread, prevention of colds, pneumonia and influenza, importance of early medical care.

January 12—Scarlet Fever, Measles and Whooping Cough: modern attitudes toward these diseases, their prevention by community cooperation.

The stations on the Red network are privileged to broadcast the program but, since it is a noncommercial program, they are not obliged to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Annual Reregistration Due January 1—Every licensee of the Arkansas Eclectic Medical Examining Board must register annually with the secretary of the board between January 1 and the last day in February and pay a fee, if a resident of Arkansas, of \$2 and, if a nonresident, of \$4. The failure of a licensee to pay the required fee by March 1 automatically suspends his right to practice while delinquent. If he fails for three successive years to pay the required fee, his license is to be canceled, and thereafter he will be reinstated only on such a showing to the board of moral character and professional qualifications as would entitle the applicant to the issuance of an original license and the payment of the same fee as is required for the issuance of an original license.

CALIFORNIA

Plague Infection in Squirrels in Fresno County—Under date of November 5, Dr. Walter M. Dickie, director of the state department of health, reported that plague infection had been proved by animal inoculation in fleas from forty-six golden mantled squirrels collected September 30 in the Cedar Crest area, two miles west of Lake Shore, Huntington Lake, Fresno County, according to *Public Health Reports*.

Society News—Dr. Morris Fishbein, editor of *THE JOURNAL*, Chicago, addressed the Los Angeles County Medical Association December 2 on "Medicine and the National Policy." A dinner in his honor preceded the meeting. A symposium on the treatment of dementia praecox was presented before the Society of Neurology and Psychiatry of Los Angeles, December 15, by Drs. Eugene Ziskind, Los Angeles, David W. Lester, Compton, Cullen Ward Irish, Los Angeles, Douglas R. Dodge, Pasadena, John B. Doyle and Samuel D. Ingham, Los Angeles.

CONNECTICUT

Annual Registration Due During January—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January, with the state department of health, and at that time to pay a fee of \$2. Licensees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

Society News—Dr. Samuel H. Epstein, Boston, addressed the New London County Medical Association October 7 at Norwich on "Treatment of Neurosyphilis." The Middlesex County Medical Association was addressed in Middletown October 12 by Dr. Richard H. Overholt, Boston, on "Surgical Diseases of the Chest." At a meeting of the Tolland County Medical Association in Somers, October 19, Dr. C. Charles Burlingame, Hartford, discussed psychiatric problems.

Aid for Crippled Children—Under the social security act, Connecticut will receive \$60,000 from the federal government to be added to a similar amount appropriated by the last session of the general assembly for the states crippled children program, according to the *New England Journal of Medicine*. The program will include the establishment of five permanent diagnostic clinics throughout the state so that they may be accessible to districts where their services are most needed.

GEORGIA

Personal—Dr. Isham W. Irwin, Albany, received a silver service from the Dawson Kiwanis Club as a token of appreciation for his work in behalf of unfortunate children in Dawson and Terrell County, according to the state medical journal.

Resolution About Anesthesia—A resolution was adopted by the Fulton County Medical Society November 18 asking that the Medical Association of Georgia, Georgia Hospital Association, University of Georgia School of Medicine and Emory University be petitioned to take action to improve the science of anesthesia. The society disapproved the sale to the public of the services of salaried, nonprofessional anesthetists.

Society News—Dr. Evert A. Bancker Jr. discussed "The Electrocardiogram and Its More Common Abnormalities in Man" before the Fulton County Medical Society, Atlanta, November 18. Dr. Martin T. Meyers presented a paper before the society, November 4, entitled "Air Injection in Joint Diagnosis."—Dr. Lewis H. Oden Jr., Blackshear, discussed "The Raw Apple Diet in Infantile Diarrhea" before the Ware County Medical Society in Waycross, October 6.—Papers were presented before the Georgia Medical Society in Savannah, October 26, by Drs. Claude M. Burpee, Augusta, and Walter E. Brown, Savannah, entitled "The Treatment of Gonococcus Infections of the Genital Tract in Girls" and "Unusual Tumor of the Ovaries, Bilateral."—The state board of health opened branch laboratories at Albany and Waycross recently.

ILLINOIS

New County Sanatorium—Dr. Charles K. Petter of the staff of the Glen Lake Sanatorium, Oak Terrace, Minn., has been appointed director and supervisor of the Lake County Tuberculosis Sanatorium shortly to be erected. He will take office about January 1. The voters of the county approved at the November 1930 election a proposition to build a tuberculosis sanatorium with tax revenue to be collected over a period of ten years starting next summer, newspapers report.

Chicago

Outbreak of Smallpox—Six cases of smallpox were discovered in the Roseland district December 11, according to the *Chicago Tribune*. Four of the patients were members of one family and the other two were neighbors. None of the patients have been vaccinated successfully, it was stated. These are the first cases of smallpox reported in the city since April.

Mobile X-Ray Unit—The Chicago Tuberculosis Institute and the Municipal Tuberculosis Sanatorium are sponsoring a traveling x-ray unit to combat tuberculosis among school children in Chicago. The unit was put into service at the Spalding School for Crippled Children recently. It contains dressing rooms and equipment for taking 400 x-ray plates a day and will be moved from school to school, newspapers reported.

KANSAS

Personal—Drs. Willard W. Nye, Eberly J. Leigh, George C. McKnight, all of Hiawatha, and Henry J. Deaver, Sabetha, were guests of honor at a dinner given by the Brown County Medical Society in Hiawatha, November 5. They are all honorary members of the society.—Dr. Charles M. Starr, Larned, has been appointed health officer of Pawnee County.

Society News—The Golden Belt Medical Society was addressed October 14 in Salina by Drs. James A. Simpson, Salina, on Podalic Venous, Harry R. Wahl, dean and professor of pathology at University of Kansas School of Medicine, on "Multiple Tumors of the Sympathetic Nervous System," Ralph H. MacKenzie, M.D., on "Nephritis and Nephrosis," and Frank K. Taylor, M.D., on "Traumatic Injuries of the Head."—At a meeting of the Pratt County Medical Society, Pratt, October 22, Dr. Newman C. Newell, M.D., discussed the treatment of infections with penicillin. Dr. Albert K. Hatcher, Wellington, discussed the maintenance of the blood.—Dr. Howard E. Snyder, Winfield, addressed the Cherokee County Medical Society in

Arkansas City, October 21, on "Treatment of Fractures of the Lower Extremities."—At a meeting of the Anderson County Medical Society in Garnett, October 20, Drs. Ralph L. White and Ray D. Fraker, both of Garnett, discussed injection treatment of hernia and the use and danger of sultanilamide respectively.

LOUISIANA

The Stanford E. Chaille Memorial Oration—Dr. Walter Timme, professor of clinical neurology, Columbia University College of Physicians and Surgeons, New York, delivered the twelfth annual Stanford E. Chaille Memorial Oration before the Orleans Parish Medical Society, New Orleans, December 6. Dr. Timme discussed "Status Hypoplasticus. Its Bearing on All Fields of Medicine and the Automatic Compensatory Mechanisms Involved."

The Rudolph Matas Medical Library—The library of Tulane University of Louisiana School of Medicine, New Orleans, was named in honor of Dr. Rudolph Matas, emeritus professor of surgery at the university, November 29. The special ceremonies paid tribute to Dr. Matas's year of service to the university and to his constant interest in the development of the library. It also marked his seventy-seventh birthday, which occurred September 12. The medical library is in the Hutchinson Memorial Building and numbers in its collection about 30,168 bound volumes, 2,500 original pamphlets, 1,900 mounted portraits, 60,000 reprints, 250 medical bookplates and an extensive collection illustrating medicine in art. The library receives currently more than 350 medical periodicals many of them through the Maurice Stern Fund. Three special collections are the Feingold Library of Ophthalmology, the Hall Library of Dentistry and the recently established Isaac Iva Lemann Collection on Diabetes. Two small rooms were used for a library and reading room as far back as 1843 when the university was the University of Louisiana. In 1893 the Richardson Memorial Building provided space for the library and in 1896 Dean Stanford E. Chaille, with two assistants began the first definite organization of a medical library. The library of the Orleans Parish Medical Society is administered with the Rudolph Matas Medical Library. At the recent dedication Rufus Carrollton Harris, president of the university, presided and Dr. Charles C. Bass, dean of the medical school gave the principal address. Dr. Matas graduated at Tulane in 1880 and was associated with it from 1895 to 1927.

MICHIGAN

Changes in Health Officers—Dr. Thomas I. Gibbon Flint, recently resigned as health officer of Genesee County to accept a similar position in Eaton County to succeed Dr. Joseph W. Davis, formerly of Charlotte, resigned. Dr. Leslie V. Burkett, Midland, formerly health officer of Midland County, has been appointed in Genesee County. Dr. Hugh B. Robins, Marshall, associate director of the Calhoun County Health Department, has been placed in charge of the department, succeeding Dr. Matthew R. Kinde, who is now at the W. K. Kellogg Foundation Battle Creek.

Society News—Dr. Frederick H. Cole, Detroit, discussed "Obstruction of the Vesical Neck" before the county medical society in St. Clair November 16.—Dr. Owen H. Wenzel, Minneapolis, addressed the surgical section of the Wayne County Medical Society November 29 on "Suction in the Treatment of Intestinal Obstruction."—Dr. Harold I. Morris, Detroit, discussed "Cancer of the Bladder" before the county medical society in Jackson November 16.—Dr. William C. MacCarty, Rochester, Minn., discussed breast tumors before the Ingham County Medical Society, Lansing, November 16.

The Novy Fellowship Fund—At a meeting of representatives of the medical classes of the University of Michigan it was decided on behalf of the alumni of the medical school to initiate a ten year campaign for the endowment of a Fredrick G. Novy Fellowship Fund for Research in Bacteriology. Dr. Novy joined the university in 1886 as assistant in organic chemistry. He became dean emeritus and professor emeritus of bacteriology in 1935. A resolution adopted at the meeting provides that the fund shall be administered by the board of regents of the university, the principal sum to remain intact and disbursements from its earnings to be made on recommendation of the director of the department of bacteriology and the executive committee of the medical school to the president of the university and the board of regents. The fund is to be used only for nonrecurrent research purposes.

MINNESOTA

Annual Registration Due During January—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January, with the secretary of the board of medical examiners, and at that time to pay a fee of \$2. A licensee who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

MISSISSIPPI

New Venereal Disease Clinic—A clinic providing free treatment to indigent persons for venereal diseases was opened in Hattiesburg in October, according to the *Health Officer*. Funds have been supplied by the state board of health and the U. S. Public Health Service through social security appropriations.

Society News—The Coast Counties Medical Society was recently formed by the amalgamation of the Harrison-Stone-Hancock Counties Medical Society and the Jackson County Medical Society, bringing all the counties in the ninth district into one organization. Dr. Edwin B. Van Ness, Gulfport, is president, and Dr. Daniel L. Hollis, Biloxi, is secretary. At a meeting of the Delta Medical Society in Greenwood, October 13, the speakers included Drs. Fred M. Sandifer, Jr., Greenwood, on 'Varicose Veins', Eugene R. Nobles, Rosedale, 'The Problem of Acute Abdominal Pain', Hugh A. Gamble, Greenville, 'Operative Treatment of Carcinoma of the Breast', George J. Mancill, Indianola, 'Obstetrics in General Practice', James W. Barkley, Belzoni, 'Immunization Against Communicable Diseases', and Gilbert F. Douglas, Birmingham, Ala., 'Study of Sterility Using the Rubin Test'. Speakers before the Clarksdale and Six Counties Medical Society, November 10, included Drs. Claude F. Varner, Memphis, on appendicitis, William P. Warfield, Clarksdale, upper respiratory infections in infants and children, and Charles S. Paddock, Memphis, ptychitis in pregnancy. Drs. William L. Little, Wesson, and Joseph E. Green, Laurel, president and president elect respectively of the state medical association, also addressed the meeting.

NEBRASKA

Bequest for Cancer Research—A public school teacher of Omaha recently bequeathed \$1,600 to the Creighton University Tumor Clinic at St. Joseph Hospital. According to the *Nebraska State Medical Journal*, this fund will be the nucleus of an endowment fund, the income from which will be for cancer research.

NEW JERSEY

Public Health Meeting—The sixty-third annual meeting of the New Jersey Health and Sanitary Association was held in Princeton, December 10-11. Among speakers at various sessions were Drs. Russell L. Cecil, New York, on 'Methods of Reducing Pneumonia Mortality', Herbert R. Edwards, New York, 'Latent Tuberculosis and Its Significance in the Control Program', William D. Stroud, Philadelphia, 'Heart Disease', and Livingston Farrand, Ithaca, N. Y., 'Health Education in Its Broader Aspects'.

Society News—The Society of Surgeons of New Jersey held its twenty-fifth anniversary meeting in Trenton, November 20. In the morning operative clinics were held at the Mercer and St. Francis hospitals. After luncheon at the Statcy-Trent Hotel, the afternoon was devoted to the showing of surgical motion pictures. Dr. Frank G. Scammell, Trenton, president of the society, presided at an anniversary dinner in the evening. Dr. George Blakburne, Newark, was elected president for the coming year, and Dr. Walter B. Mount, Montclair, was reelected secretary.

State Board Activities—Among unlicensed practitioners convicted through activities of the state board of medical examiners in recent months are the following reported in November:

Rash Cruso, who was treating foot ailments in a shoe store in Jersey City.

Percy Ridout, an unlicensed chiropractor of Englewood.

John E. Usher, a licensed chiropractor of Orange who was practicing electrotherapy.

Israel Shind, a naturopath of Lakewood, found guilty on a similar charge in 1929.

Nathan H. Fleischer, a registered pharmacist of Englewood.

Paul Piekarsky, a licensed chiropractor of Paterson.

Frank Sinduzzi, a registered pharmacist of Newark.

George Maza, an unlicensed chiropractor of Newark.

James A. Conroy, registered pharmacist of Moorestown.

Nicholas Tarmaki, Orange, who gave his patients medicine prepared by himself.

NEW YORK

Medical Building Dedicated—The new building of the Syracuse University College of Medicine was dedicated November 22 with ceremonies in the auditorium of the building. The speakers were:

Dr. Henry A. Christian, Hersey, professor of the theory and practice of physics, Harvard University Medical School, Boston; The Frutkin of the Clinician.

Dr. Edward S. Godfrey, Jr., state health commissioner, Albany; The Medical School in the Field of Public Health.

Dr. Ray Lyman Wilbur, president of Stanford University, California, and chairman of the Council on Medical Education and Hospitals, American Medical Association; The March of Medicine.

The alumni held their annual reunion in the building November 20 and there was open house for the citizens of Syracuse November 21. The five-story building, financed by a PWA loan of \$850,000, was designed in English Georgian style by the late James Russell Pope and Dwight James Baum. Laboratories, classrooms, lecture rooms and departmental offices open off three main corridors on each floor, each department's laboratories, classrooms and offices are adjoining. An auditorium seating 400 is on the first floor at the rear of the building. The college library occupies two floors in one wing. The top floor is devoted to the Hendricks Research Laboratory for research in infant feeding. Ground was broken for

New Medical School Building and the Syracuse Memorial Hospital

the new building June 2, 1936, and President Franklin D. Roosevelt laid the cornerstone the following September 29. It is the fourth unit in a plan for a medical center initiated by the college in 1925. Previously completed are the Syracuse Memorial Hospital, shown at the right of the photograph, the State Psychopathic Hospital and the city communicable disease hospital.

New York City

Foundation Opens New Departments—The Hecksher Foundation for Children with headquarters at Fifth Avenue and One Hundred and Fourth Street, announces establishment of a department of hygiene and preventive medicine under the direction of Dr. Heinz R. Landmann. It has also opened a child guidance clinic under the direction of Jacob S. List, Ph.D., a psychologist. Dr. Landmann graduated from the University of Bern, Switzerland in 1934 and was licensed in 1935. The Hecksher Foundation for Children was established in 1921 by August Hecksher.

Promotions at New York University—Dr. Karl M. Bowman was recently promoted from professor of clinical psychiatry to professor of psychiatry to succeed Dr. Menas S. Gregory, now professor emeritus, at the New York University College of Medicine. Dr. Joseph Edward Connery has been promoted to be professor of clinical pathology to succeed the late Dr. Arthur R. Mandel, and Dr. Clarence L. de la Chapelle is acting chairman of the department of medicine. Other promotions are: Drs. Emery A. Rovenstine to be professor of anesthesia in the department of surgery; Lauretta Bender, clinical professor of psychiatry; Frank J. Curran, assistant clinical professor of psychiatry; and Joseph Goldstein, assistant clinical professor of pediatrics.

Medal to Honor Dr. Snow—At a dinner in honor of Dr. William F. Snow, managing director of the American Social Hygiene Association, October 1, at the Waldorf-Astoria, Dr. Snow was presented with a bronze medallion portrait of himself. It is planned to strike a medal from the original sculpture and to award it from time to time as the William Freeman Snow Medal for Distinguished Service in Social

Hygiene A committee of the board of directors of the association will make the awards. Speakers at the dinner were Major-Gen. Merritt W. Ireland, Washington, D. C. who was toastmaster, Dr. Wilbur A. Sawyer, Sir Arthur Newsholme, London, Miss Katharine F. Lenroot, director of the Children's Bureau, Washington, D. C., Dr. Livingston Farrand, former president of Cornell University, Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., and Dr. John H. Stokes, Philadelphia. Dr. Edward L. Keyes presented the medal.

NORTH CAROLINA

Correction—Annual Registration of Physicians—The item in THE JOURNAL last week under North Carolina with respect to the annual registration required of physicians was in error. The item should have appeared under North Dakota. Physicians in North Carolina are not required to register annually.

Sanatorium Dedicated—A new state sanatorium for tuberculosis, built with PWA assistance at a cost of \$625,000 on Black Mountain near Asheville, was dedicated November 11 with an address by Gov. Clyde R. Hoey. Dr. Paul P. McCain is superintendent of the new 165 bed institution. Dr. Samuel M. Bittinger is medical director and associate superintendent. Dr. McCain is also in charge of the state's other public sanatorium, of 480 beds, known as the North Carolina Sanatorium for Treatment of Tuberculosis at Sanatorium, near Raeford in Hoke County, and Dr. Bittinger has been assistant superintendent and associate medical director.

NORTH DAKOTA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5 if a resident of North Dakota or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and 50 cents for each month of default.

OKLAHOMA

Society News—At the annual joint meeting of the Garfield County Medical Society and the Northwestern District Dental Society in Enid, November 18 the speakers were Charles R. Lawrence, D.D.S. Enid, on 'The Relations of the Dentist and the Physician in Care of the Patient' and Dr. James D. Osborn Jr. Frederick, secretary of the state board of medical examiners who discussed an initiative bill proposing to change the composition of the state board.

PENNSYLVANIA

Society News—Dr. Bertram M. Bernheim, Baltimore, addressed the York County Medical Society, York, November 20 on 'Diagnosis and Treatment of Peripheral Vascular Disease'. Drs. John B. Nutt and Thomas Marshall West addressed the Lycoming County Medical Society, Williamsport, December 10, on 'Toxemias of Pregnancy' and 'Treatment of Bladder Tumors' respectively. Dr. Othello S. Kough, Uniontown, gave an address and demonstration on 'Artificial Pneumothorax in the Treatment of Tuberculosis' before the Fayette County Medical Society, Uniontown, December 2. At the annual dinner of the Cambria County Medical Society, Johnstown, December 9 Judge John H. McCann, Ebensburg, spoke on 'The Doctor and the Law' and Dr. Olm G. A. Barker, Johnstown, showed motion pictures 'Through Africa from Cairo to Capetown'. The Harrisburg Academy of Medicine has purchased a larger building for its headquarters.

Philadelphia

Personal—Members of the Proctologic Society of the Graduate Hospital gave a dinner November 20 in honor of Dr. Collier Ford Martin, professor and vice dean of proctology, University of Pennsylvania Graduate School of Medicine. The speaker included Dr. William Wayne Babcock, Edwin S. Clark and Wilmer Kruken, Philadelphia; Clement L. Martin, Chicago; Deacon C. McKee, Lumbago; Frank C. Yeomans, New York; William H. Herrick, Richmond, Va.; Dr. Harry J. B. F. Philadelphia chairman.

Dean Charles H. LaWall Dies—Charles Herbert LaWall, born in Philadelphia, attended the University of Pennsylvania College of Medicine and served as a resident in the department of medicine from 1907 to 1910. He was

appointed instructor at his alma mater. In 1906 he was an associate professor of the theory and practice of pharmacy and in 1918 succeeded Joseph P. Remington as dean. For many years Dr. LaWall was chemist for the bureau of food and chemistry of the Pennsylvania Department of Agriculture and the Pennsylvania Board of Pharmacy. He was elected to the revision committee of the U. S. Pharmacopeia in 1910 and served continuously on subsequent committees including two years as chairman. He was also associated with the revision committees of the National Formulary and the U. S. Dispensatory. Among honors conferred on Dr. LaWall were the Remington Medal of the American Pharmaceutical Association and honorary degrees from the University of Pittsburgh and Susquehanna University. He was president of the American Pharmaceutical Association in 1919 and the American Association of Colleges of Pharmacy in 1923. During the World War he was a member of the auxiliary committee on drugs and medicine of the War Industries Board. Dr. LaWall was also co-editor of the seventh and eighth editions of Remington's 'Practice of Pharmacy'.

WEST VIRGINIA

Society News—Dr. Walter N. Rowley, Huntington, addressed the Fayette County Medical Society, Montgomery, November 9, on 'Estrogenic and Gonadotropic Hormone Therapy'. Dr. William F. Rienhoff Jr., Baltimore, addressed the Harrison County Medical Society, Clarksburg, November 4 on diseases of the gallbladder and gall ducts. Dr. William F. Snow, New York, spoke briefly on the syphilis campaign. Dr. Amos H. Stevens, Fairmont, addressed the Monongalia County Medical Society, Morgantown, November 2 on 'Prognosis and Late Manifestations of Rheumatic Heart Disease'.

New Quarters for Radiologic Clinic—The Huntington Radium and X-Ray Clinic opened new quarters in the Memorial Hospital, Huntington, November 11, with public inspection in the afternoon and a dinner meeting of the Cabell County Medical Society in the evening. Dr. Edwin A. Merritt, Washington, D. C., gave an address on 'Preoperative Radiation: a Therapeutic and Diagnostic Measure,' which was discussed by Dr. Henry Schmitz, Chicago. The clinic now has a high voltage therapy x-ray machine of 220,000 volts. Dr. James Edward Hubbard is director and Dr. Walter Beckett Martin is associate director of the clinic, which was founded in 1921.

GENERAL

Meeting of Psychoanalytic Association—The thirty-ninth meeting of the American Psychoanalytic Association will be held in Washington, D. C., December 27-28 with headquarters at the Hotel Shoreham. Among the speakers will be:

Dr. Sándor Rado, New York, 'Etiology and Treatment of the Neurosis'; Dr. Felix Deutsch, Boston, 'Pain as a Psychosomatic Problem'; Dr. Lucia E. Tower, Chicago, 'Premature Birth as a Factor in Development of a Paranoid Depressive Mechanism'; Dr. Helen Flanders Dunbar, New York, 'Psychoanalysis and the General Hospital'.

Bequests and Donations—The following bequests and donations have recently been announced:

Mount Sinai Hospital, New York, \$10,000 by the will of Mrs. Cyrus L. Lehman; Hospital for Joint Diseases and Montefiore Hospital, New York, \$7,000 each by the will of Samuel Frank; Sinai Hospital, Baltimore, \$10,000 and his medical library by the will of the late Dr. Harry Adler; Presbyterian Hospital, New York, \$10,000 by the will of Henry T. Sloane; Germantown Dispensary and Hospital, Germantown, Pa., \$5,000 by the will of the late Jane Harmer at the termination of a trust.

Meeting of Medical Students—The fifth annual convention of the Association of Medical Students will be held at the medical schools of the University of Chicago and the University of Illinois, December 29-31. Addresses of welcome will be delivered by Drs. Basil C. H. Harvey, dean of medical students, Division of Biological Sciences, University of Chicago; David J. Davis, dean, University of Illinois College of Medicine; and Olm West, Secretary and General Manager, American Medical Association. Panel discussions, lectures and clinics will make up the program. Special features will include tours of the medical schools and the Headquarters of the American Medical Association.

Special Board Examination—The American Board of Obstetrics and Gynecology announces that the next examination for group B candidates who have filed applications will be held in various cities of the United States and Canada, July 1938. This is the written examination and review of case histories. The general oral clinical and pathologic examinations for all candidates (groups A and B) will be conducted by the entire board in San Francisco, June 13-14, immediately before the annual session of the American Medical Association.

Applications for admission to the June 1938 group A examinations must be on an official application form and must be filed with the secretary before April 1, 1938. For further information and application blanks address Dr Paul Titus, secretary, 1015 Highland Building, Pittsburgh.

Biography of Reginald H Fitz—Dr Hyman Morrison, clinical professor of medicine, Tufts College Medical School, Boston, is gathering material for a biography of Reginald Heber Fitz (1843-1913) and requests the assistance of THE JOURNAL in reaching readers who knew Dr Fitz personally or who may have some of his correspondence. Dr Morrison writes that he will be responsible for the safe return of any letters sent to him. Dr Fitz graduated at Harvard University Medical School in 1864 and spent several years in European centers. He returned in 1870 and joined the faculty at Harvard. He was active in the affairs of the school and his clinical work produced important results. In 1886 he published the article in which he established the importance of perforation of the appendix. He retired from Harvard in 1908 as professor of medicine and died Sept 30 1913.

Society News—Dr Robert Tait McKenzie Philadelphia was elected president of the Academy of Physical Medicine at its annual meeting in Philadelphia in October. Drs Rolland A Case, Cleveland, and William H Schmidt, Philadelphia were elected vice presidents and Dr Herman A Osgood Boston, secretary. The next annual session will be in Washington, D C.—Dr James W Jervy Greenville S C, was elected president of the Southern Medical Association at its annual meeting in New Orleans November 30-December 3, and Drs Lucien A Le Douv, New Orleans, and Lee Rice, San Antonio, Texas, were elected vice presidents. The next meeting will be held in Oklahoma City.—A meeting of the secretaries of the sections of the American Association for the Advancement of Science and those of the affiliated societies will be held at the Claypool Hotel Friday, December 31, during the annual session of the association.

Western Surgical Association—Dr Casper F Hegner Denver, was elected president of the Western Surgical Association at its annual meeting in Indianapolis, December 3-4. Drs Charles L Patton, Springfield Ill and Verne C Hunt, Los Angeles, were elected vice presidents and Dr Albert H Montgomery, Chicago, was reelected secretary. The 1938 convention will be in Omaha. Among speakers on the program were

Dr John Alexander Ann Arbor Mich The Indications Technique and Results of Surgery for Bronchiectasis
Dr Angus L Cameron Minot N D Primary Malignancy of the Jejunum and Ileum
Dr Charles W Mayo Rochester Minn A New Method of Repair of Complete Rectal Prolapse
Dr Fred F Attix Lewistown Mont Purulent Pericarditis Due to the Pneumococcus
Dr Edgar L Gilchrist San Francisco Lesions of the Shoulder
Dr Kellogg Speed Chicago Spondylolisthesis
Dr Claude J Hunt Kansas City Mo Pancreatic Cyst
Dr Gordon S Fahrni Winnipeg Manit Hyperparathyroidism

Pan American Cruise Congress—The seventh cruise congress of the Pan American Medical Association will leave New York January 15 and return January 31. Among speakers from the United States will be

Dr William D Haggard Nashville Technic in Treatment of Fibroid Tumors
Dr Chevalier Jackson and Chevalier L Jackson Philadelphia Cancer of the Larynx
Dr Edwin C Ernst St Louis Recent Developments in Relation to the Radiation Management of Cancer
Dr Webb W Weeks New York Operation for Chronic Simple Glaucoma
Dr Howard R Hartman Rochester Minn Treatment of Hemorrhagic Ulcer of Stomach or Duodenum
Dr Henry D Furniss New York Urinary Incontinence in Women
Dr Joseph J Eller New York Cosmetic Results in Treatment of Skin Tumors
Dr James Ewing New York Cancer Pathology
Dr Jerome Webster New York Plastic Surgery Technique
Dr Herman N Bundesen Chicago Amebiasis
Dr Lee M Hurd New York Sinus Operations
Dr Fred H Albee, New York Surgical Restoration of Motion in Bony Stiff Joints

Among other speakers will be Dr Jose Arce, Buenos Aires, Argentina, on "Twenty Years in Chest Surgery."

Academy of Orthopaedic Surgeons—The sixth annual meeting of the American Academy of Orthopaedic Surgeons will be held at the Hotel Biltmore, Los Angeles January 17-20 under the presidency of Dr Arthur Bruce Gill, Philadelphia. Registration will begin Sunday afternoon at 2 o'clock, January 16. A special train on the Atchison, Topeka and Santa Fe Railroad will leave Chicago January 10 at 10 15 a m. There will be a clinical demonstration Monday morning January 17 and scientific sessions will begin in the afternoon. There will be symposiums on nonunion and bone grafts fractures of the spine and manipulative surgery. Among the

speakers on the program will be Drs Norman T Kirk and Howard C Naffziger, San Francisco, Willis C Campbell, Memphis, Tenn, Melvin S Henderson, Rochester, Minn, Edwin W Ryerson, Chicago, George E Bennett, Baltimore, William B Carrell, Dallas, Texas, Arthur G Davis, Erie, Pa, William V Cone and William George Turner, Montreal, Philip D Wilson New York, Johan H Waldenstrom, Stockholm, Sweden, and H Watson Jones, Liverpool, England.

Symposium on Syphilis—Section N, the Medical Sciences of the American Association for the Advancement of Science will devote its entire program at the meeting, December 27-January 1, to a symposium of twenty-nine papers on syphilis. The papers are grouped in sessions on the following topics: historical the causative agent closely related agents, immunity, pathology, various forms of the disease, diagnostic aids, treatment, chemotherapy and toxicity of drugs. Among the speakers will be

Dr William Allen Pusey Chicago The American Origin of Syphilis
Dr Norman R Ingraham Jr Philadelphia Spirochaeta Pallida and the Etiology of Syphilis
Dr John A Kolmer Philadelphia Serologic Reactions in Relation to Infection and Treatment of Syphilis
Dr Paul A O Leary Rochester Minn Neurosyphilis
Dr Charles C Dennis Kansas City Mo Congenital Syphilis
Reuben L Kahn Sc D Ann Arbor Mich The Outstanding Features of the Kahn Antigen
Dr Benjamin S Kline Cleveland The Outstanding Features of the Kline Antigen
Dr Walter M Simpson Dayton Ohio High Temperatures
Dr Harry Eagle Baltimore The Direct Spirochetostatic and Spirocheticidal Action of the Arsphepnamines
Dr Dudley C Smith University Va Untoward Reactions—Intercurrent Infections

Dr Thomas Parran, surgeon general, U S Public Health Service, Washington, D C, will address a general session of the association on "Syphilis A Public Health Program."

Medical Bills in Congress—*Bills Introduced* S 3098 introduced by Senator Capper, Kansas, proposes to provide for uniform regulation of marriage and divorce. The bill provides, among other things, that no license to marry shall be issued to a person who is insane or an imbecile, pauper, epileptic, feeble-minded or afflicted with tuberculosis or a venereal disease. S 3120, introduced by Senator Walsh, Massachusetts proposes to authorize the President to appoint for temporary service in the Navy 100 acting assistant surgeons, who shall have the rank and compensation of assistant surgeons. H Res 375 submitted (by request) by Representative Stack, Pennsylvania, proposes to provide That all World War veterans' service records become an official part of their medical record so that the Veterans Administration must consider any ailment, from which a veteran may be suffering, not proven as service connected by his medical record, to be established as service-connected by consideration of his service record." H R 8655, introduced by Representative Dunn Pennsylvania, proposes to authorize an appropriation of \$200,000,000 for the prevention and cure of cancer, infantile paralysis, tuberculosis, blindness, deafness and "other social diseases." H R 8641, introduced by Representative Palmisano, Maryland, proposes to provide that any honorably discharged ex-service man who entered the service prior to Nov 11 1918 and served ninety days or more during the World War, and who is or may hereafter be suffering from a 25 per centum or more permanent disability not the result of his own willful misconduct which was not required in the service during the war, or for which compensation is not payable shall be entitled to receive a disability allowance at prescribed rates.

CANADA

North Pacific Surgical Association—The annual meeting of the North Pacific Surgical Association was held in Vancouver B C, November 18-20, with Dr William E Gallie, professor of surgery, University of Toronto Faculty of Medicine, Toronto, as the guest speaker. Dr Andrew A Matthews, Spokane Wash, was elected president, Drs Gordon C Kenning, Victoria, B C, and Robert D Forbes Seattle were elected vice presidents and Karl H Martzloff Portland, Ore is secretary.

Orthopedic Service for Paralysis Victims—The department of health of Saskatchewan has established a special orthopedic service at the Grey Nuns' Hospital, Regina for treatment of residual paralysis arising out of a recent outbreak of poliomyelitis. The plan includes three weeks of treatment with medical and hospital care and transportation paid and special splints gratis. It is also a part of the plan to have the child's mother or some responsible person spend three days at the hospital for instruction in continuing the treatment at home. It was estimated that out of 445 cases of poliomyelitis there would be at least 100 patients requiring treatment.

The Annual Health Report

In his annual report, just published, Sir Arthur MacNalty, chief medical officer of the Ministry of Health, compares the vital statistics of today with those of a century ago. In 1936 the crude death rate was 12.1 per thousand against 22.4 in the eighteen forties, the infant mortality 59 per thousand live births against 153. The number of infants who died under 1 year of age, 35,425, was less than half the number who would have died under the conditions as recent as thirty years ago. The death rates for both respiratory and nonrespiratory tuberculosis were in 1936 the lowest on record. The standardized death rate from all forms of tuberculosis was 657 per million, against 3,476 in the fifties of the last century. It is noted as "particularly satisfactory" that the mortality from tuberculosis among young women, which showed some increase, is again declining and at an increasing pace.

In 1936 the birth rate was 14.8, a slight increase on the 14.7 of 1935 and 0.4 above that for 1933, which was the lowest on record. The five principal causes of death remain the same as for many years and in the same order: (1) diseases of the heart and circulatory system, (2) cancer, (3) respiratory diseases, (4) diseases of the nervous system and (5) tuberculosis. But between the ages of 15 and 65 tuberculosis takes the third place and diseases of the nervous system the fifth. The proportion of deaths from heart and circulatory diseases has steadily risen during the past five years. During the same period the proportion of deaths from tuberculosis has steadily fallen; the cancer mortality has risen.

It was claimed not long ago that typhoid had practically vanished from this country because of improved sanitation, but a serious increase has recently taken place. In 1936 there were 2,490 notifications (including paratyphoid) with 257 deaths. In 1935 the corresponding figures were 1,750 and 174. At present a serious outbreak is in progress in Croydon, a town near London. It has been noted that contaminated well supplies drinking water. Eighteen persons have been reported today having died, and up to 177 with six deaths. The disease has appeared also in London.

The maternal mortality in 1936 was 365, a slight reduction from 394 for 1935, which again was a reduction from 441 for 1934. Puerperal sepsis accounted for 134, leaving 231 for other causes. Abortion, which appears to be frequent and increasing, is responsible for a number of deaths from puerperal sepsis.

A section of the report is devoted to poisoning from lipsticks and their contents. It is pointed out that it is desirable to determine the ingredients which the patient is sensitive, since a formula without the offending ingredient enables the application to be resumed with impunity. The doctor is mostly at fault, and that most frequently incriminated is cream. Hair dyes of vegetable origin cannot be incriminated, but those which depend on formaldehyde or formalin or its derivative might give rise in some cases to poisoning. It is pointed out that eye makeup, eye-lash stains, eye lotions and eye ointments, and eye drops, and eye-circum-

of an advisory nature has been sent by request to Austria, Belgium, Burma, Canada, Ceylon, Denmark, Egypt, France, Germany, India, Italy, Jamaica, Kenya, Lithuania, New Zealand, Poland, Rumania, South Africa, Sweden, Switzerland and the United States. The national register of leaders in Britain now includes about 3,000 names. To meet the immediate need in the training and provision of leaders, short courses have been held in the evenings or week ends or during vacation. Half-day training courses have proved of great value. This concentrated form of instruction not only gives already trained teachers new material but also arouses enthusiasm. The council considers that 1937 will stand out as the year of national awakening to the urgency of universal physical recreation. This it attributes largely to the work of those individuals and organizations who have labored untiringly toward that end for many years and to further whose efforts the Central Council has offered the strength of coordinated action. Influences from many foreign countries have also been at work and a splendid press campaign has set the seal on success. "Complete fitness in the individual," the report says, "is unfortunately rare. Too often physical and mental well-being are betrayed by moral weakness, or there is mental strength with bodily disability, or else physical and moral health is accompanied by weak mentality. The aim must always be toward the highest, which is perfect ability in every sphere—fitness for life, not merely fitness for games. Such a comprehensive conception presupposes full observance of enlightened rules of nutrition and hygiene."

The Government and Precautions Against Air Raids

The local authorities have objected to bearing so much of the cost of the precautions to protect the civilian population against air raids. The government has therefore undertaken the greater part of the cost. In a memorandum it points out that it has already assumed a substantial liability in the supply of respirators for the whole civilian population, the maintenance of anti-gas training schools, the supply of bleaching powder for decontamination and the provision of protective clothing for the air raid services. It now proposes to pay the whole cost of most of the material and equipment for these. It proposes to ask the local authorities to assume a share of the responsibility only in those matters in which they will administer. The government will make grants to an extent varying from 60 to 75 per cent of the expenditure of the local authorities on air raid precautions. These include the repairing of streets damaged by air raids, the control of lights, decontamination work and fire fighting. The government will provide such fire fighting apparatus as may be necessary for emergency purposes. It will also provide stretchers, blankets, the equipment needed for decontamination and rescue parties, and the equipment and stores for first aid posts and casualty clearing hospitals. On the other hand, the local authorities will undertake the services for which provision cannot be made centrally: structural precautions in public buildings, the provision of public refuges, the organization of local services, training of personnel for decontamination, emergency fire fighting, rescue and repair work and the provision of first aid.

The Aborigines of Australia

It has long been thought that like the Tasmanians the Australian aborigines will not survive the coming of the white man. Recently some 1,800 sent a petition to the king asking him to save them from extinction and empower one of their own people or a sympathetic white inhabitant to represent them in the federal parliament. The causes of their decline are various. The occupation by the white colonists of land over which the natives once hunted and roamed freely has led to their tribalization. They have taken to living in squalid camps on the fringes of bush or cattle stations where they lose interest in life and contract the diseases of the white man. Many will not receive the medical help provided by the government and run in fear

the physical
and abroad
among has
information

at the mention of the "doctor man," whose work they regard as a kind of sorcery. An alarming fact recently discovered by anthropologists is that tribes which have not been disturbed in the remote parts of the continent are restlessly moving off their traditional lands and that some of them are drifting into areas of white settlement, where their fate seems only too certain. Prof F. Wood Jones, the anatomist and anthropologist, who has vacated his chair at Melbourne University for one at Manchester, made a scathing indictment of Australia's neglect of her aborigines in his farewell address to the Victorian Anthropological Society. He said that when the white colonists arrived in 1788 there were 300,000 aborigines living healthily and happily. Today there were 50,000 with many half castes, who were existing miserably. The dole had pampered natives already degraded. There should be a central anthropologic administration of the natives with medical attention and better social conditions. The government has not entirely neglected the native problem, as Prof Wood Jones seems to imply, and has supplied both grants and medical attention, but the help has not been sufficient.

PARIS

The Annual Congress of Urologists

The thirty-seventh annual congress of the French Urologic Association was held October 4-9 at the Paris Medical School under the presidency of Dr Lepoutre of Lille. As is customary in France, one or more subjects are chosen by vote of the members at the previous year's meeting. One or two members are then appointed by the president to prepare a complete analysis of the literature of the respective subject, including personal observations. This report is sent to each member in printed form about a month before the following year's meeting, so that those who take part in the discussion can be prepared. The subject chosen for the 1938 congress is evaluation of transurethral resection, and for the 1939 congress the treatment of malignant neoplasms of the kidney. The subject chosen for this year was the surgical treatment of nephritis.

This report was read by Drs Chabanier, Gaume and Lobo-Onell, who constitute the medical and urologic members of a team especially interested in developing the surgical aspects of medical nephropathies, as they are termed here, viz of nephritis and hypertension. Failure of medical treatment to check the progress of the renal changes appeared to Harrison and Edebohl to be an indication for operative intervention. The lack of an adequate classification and reliable functional tests soon led to discarding surgery until recently when renewed interest has been shown. In addition to nephrotomy and decapsulation, other procedures such as denervation, adrenalectomy and splanchicotomy have been employed to relieve hypertension. The report was based largely on an analysis of 117 personal observations. The first question that presented itself at the onset of their work was to find a classification. That of Vidal, which was based on the functional syndromes, did not appear as satisfactory as that of Volhard and Fahr, which the authors of the report have had occasion to verify by biopsy in 250 cases of different types of nephritis.

According to Volhard and Fahr there are four principal types of nephritis: (a) glomerulonephritis, (b) the nephroses (c) the nephro-angioscleroses and (d) interstitial nephritis of infectious origin. There are two groups under the heading glomerulonephritis: one in which the changes are diffuse and another in which they are focal. Both of these are most frequently secondary to buccopharyngeal infections. In the acute diffuse form the clinical picture is that of a slight edema, hematuria, slight rise of blood pressure, moderate albuminuria and casts, lasting from fifteen to twenty days. Volhard believes that the condition persists in 30 per cent, but the authors found this to be true of a far greater number of cases. In the

chronic diffuse form, decapsulation has been followed by marked improvement in the hematuria, in pain and in lessening the frequency of acute exacerbations so frequently observed in this group. The salient feature of focal glomerulonephritis is hematuria due to degenerative glomerular lesions. Uncomplicated cases in this group had not been seen by the authors, and the value of operation in cases reported as "nephrites hematuriques" was open to doubt as long as they had not been checked by microscopic study.

In the second principal Volhard and Fahr type, which includes the nephroses and amyloses, decapsulation has been successful in only a few cases of mercurial origin. This is true also in an occasional case of lipid nephroses.

In the nephro-angiosclerosis type there are two groups, a benign one in which the hypertension is the only symptom corresponding to sclerotic changes in the renal arteries and a malignant form or hypertension associated with rapidly progressive involvement of renal function and endarteritis. Denervation performed by the authors in forty cases was followed by a drop in blood pressure, often quite marked, but which was of only a few months' duration. There is, however, a striking improvement in the general condition of the patient and an appreciable interval in the evolution of the disease. In forty-five published adrenalectomies, to which the authors added two personal observations, the operation seems to have been followed by improvement similar to that noted after denervation. In the absence, however, of any microscopic evidence in the majority of the reported cases, it is difficult to decide as to the nature of the underlying pathologic lesions. Preference is to be given to denervation except in cases of adrenal tumor.

In the fourth Volhard and Fahr type the nonsuppurative infectious type of interstitial nephritis, no typical clinical picture is found except in the cases in which an oliguria or anuria corresponds to edema and round cell infiltration in the renal interstitial tissue. Eleven personal cases of secretory anuria, verified by finding edema in the biopsy specimens, were reported. In all the cases, although there was a marked temporary increase in the output of urine, only two patients recovered. They found twenty-three reports of secretory anuria of varying etiology without microscopic control in which recovery followed either decapsulation or nephrotomy. Intervention is indicated if the anuria is of more than three days' duration and should be combined with medical treatment. The conclusions of Volhard and Fahr are that operative intervention yields results in medical nephritis which are beyond all doubt, even in cases in which little can be expected of such treatment. The control of all surgical cases ought to be made by microscopic examinations of sections of tissue removed at operation. If surgery is to be of any help, one must not wait too long before employing it. The discussion was opened by Professor Chevassu of Paris who doubted the value of biopsy because of the fragility of the convoluted tubules. He emphasized the necessity of a cytobacteriologic examination of the urine in nephritis. If there is a marked increase in the number of leukocytes a diagnosis of an infectious origin must be made, but there were many cases of infectious nephritis in which as few leukocytes are found as in the suppurative hematogenous cortical form. Cases of nephritis of apparently infectious character call for treatment of the upper respiratory tract by specialists, because the primary focus is in the nasopharynx and unless such a focus is eliminated, the nephritis will not improve.

Le Clerc Dandoy of Brussels maintained that abnormal mobility of the kidney plays an important part in essential hematuria or nephritic hematurique. Orthostatic albuminuria is often due to the passive hyperemia in movable kidney.

Louis Michon of Paris based his conclusions on thirty personal observations. At the onset of an acute glomerulonephritis, decapsulation often improves and in some cases will cure the condition. In anuria due to acute glomerulonephritis, early

bilateral decapsulation is to be recommended. Even in acute mercurial nephrosis, decapsulation in conjunction with the administration of saline solution and sodium bicarbonate solution aids in increasing diuresis. He had never observed any benefit from decapsulation in acute exacerbations of the chronic types of nephritis. Denervation is a much simpler method of treatment of hypertension than adrenalectomy or splanchnec-tomy and equally efficacious. The immediate result is satisfactory, but it has not proved to be permanent in a single case. Perhaps the end results would be better if such cases came to operation earlier.

Darget of Bordeaux stated that the three indications for operative intervention in chronic nephropathies were (1) anuria and oliguria, (2) hematuria and (3) hypertension. There is no difference of opinion as to the value of decapsulation in acute glomerulonephritis and in interstitial nephritis. In hematurias it is advisable to give transfusions before a decapsulation. Denervation in two sittings is indicated for cases of nephro-angiosclerosis. At the same time, the adrenal should be examined for marked pathologic changes calling for adrenalectomy.

Other papers read at this year's urologic congress which were of special interest included the following:

Chevassu of France recommended the use of retrograde ureteropyelography as a check on functional tests and cyto-bacteriologic examination of the urine in determining the functional capacity of a kidney before operation. He based his opinion on 7,000 cases, having found that, when there was a difference in the function tests between the two kidneys, retrograde ureteropyelography always yielded information as to which was the diseased side and the character of the lesion. Excretory urography had proved to be of little value in many cases because the visualization was often too indistinct to war-rant the drawing of any conclusions.

Dos Santos of Portugal recommended nephrectomy as soon as a diagnosis of infarction of the kidney due to embolism or thrombosis of the renal artery or vein had been made. Too long a delay was likely to favor extension of the thrombosis to the vessels of the opposite kidney.

Professor Tiffeneau Appointed Dean of Medical School

At the October 28 meeting of the faculty of the Paris Medical School the pharmacologist Prof. Marc Tiffeneau was elected as the successor of Professor Roussy, the former dean, who has recently been promoted to the presidency of the University of Paris, better known to foreigners as the Sorbonne. Professor Tiffeneau became a member of the faculty of the medical school in 1910, being appointed at that time associate professor of pharmacodynamics and later occupying the chair of pharmacology. Professor Tiffeneau has an international reputation as an authority on the problem of the relations of chemical composition and pharmacodynamic action, which study has led to the discovery of new pharmaceutical preparations. He has lectured in many foreign countries and is a member of several commissions of the League of Nations one for the biologic evaluation of drugs and others for the control of opium consumption. He has also been a fellow of the Academy of Medicine since 1927.

Tuberculin Skin Reactions in Girls

At the June 12 meeting of the Paris Tuberculosis Society, Ritt and Tuchula said that an investigation among students between the age of 20 and 22 years had given the following result: A tuberculin skin test for Nurses 27 per cent of 111 pupils of the University of Medicine gave a positive reaction. At the Social Service School the reaction was 27 per cent of 111 students, and at the University of Medicine 27 per cent of 111 students. In the discussion, Cureux reported a similar examination of a larger number of pupil nurse and medical student. Among the former, the

percentage of negative reactions varied from 29 to 30 and among the medical students it was 33. In closing Flierny Bernard insisted that a long rest period should be granted every pupil nurse who had a negative skin reaction. This was also the opinion of the phthisiologist Rist.

Annual Report on Sickness Insurance

The annual report for 1936 on the various sickness insurance organizations of Austria contains many instructive data. The Workers' Sickness Insurance Club of Vienna for example includes among its membership 317,000 directly insured workers and 236,000 relatives of the insured, a total of 553,000 persons. The sum of 4,560,000 Austrian shillings was expended for sick benefits to the directly insured workers and 610,000 shillings for benefits to workers' relatives. These benefits included both general and special medical services. If to the foregoing sums is added the 1,150,000 shillings disbursed for dental care the grand total amounts to 6,300,000 shillings (more than \$1,200,000) or 19.5 per cent of the club's entire income.

The second largest sickness insurance club, that of the federal employees, has a membership of 350,000, with 217,000 in Vienna alone. The ratio of direct insured members within this group to the insured's relatives is 53 per cent to 47 per cent. Expenditures for medical care (general and special) amounted to 7,250,000 shillings (around \$1,500,000) or 32 per cent of all funds disbursed by the club. Another 2,500,000 shillings (\$500,000) or 11 per cent of all disbursements went for dental care. Therapeutic substances and appliances requisitioned by its members cost the club 2,750,000 shillings, or 13 per cent of expenditures, 21 per cent of the club's income was paid to general practitioners, more than 12 per cent for dental care. In comparison with former years an increase in the number of claims for services of specializing physicians as distinguished from general practitioners has been discernible. The expenditure for pharmaceutical substances and so on was less than 3,000,000 shillings, in contrast to 3,500,000 shillings in the preceding year. Nearly 4,500,000 shillings was spent on hospital care for members. The 1936 statistics show an obvious diminution in the costs of sickness when compared with the figures for previous years. The explanation for this must lie in a generally more favorable condition of health among club members. Already the membership is being drawn from better social strata.

Another similarly organized sickness insurance club is composed of municipal employees of Vienna. It numbers 76,000 directly insured persons and their dependents. In 1936 this club spent 2,000,000 shillings for medical care, namely, 37 per cent of all its disbursements. It is interesting to compare the amounts expended by this club for general and for special medical care. In 1936 there was an average per claimant of 369 office calls on and 156 house visits from the general practitioners, as against 103 office calls on and 015 visits from the specialist. A member might choose from among approximately 2,500 general practitioners and 700 specialists. The report also includes analogous data on various minor sick insurance organizations in Vienna. Among the groups represented in the minor clubs are apprentices, assistants and other workers in agriculture, in the butcher trade and in hotels and similar small corporations. The average expenditure of these clubs is fairly constant amounting to from 18 to 20 per cent of the annual income. Naturally the compensation of the physician who serves one of these minor clubs will be commensurately smaller. The income per physician from this type of practice scarcely averages more than 50 or 60 shillings monthly as against the average monthly incomes of from 300 to 400 shillings enjoyed by the doctors attached to the larger insurance club. There are, however, a fairly large number of so called upper bracket r

who are able to realize more substantial incomes from practice among the minor clubs. Many specialists in particular (such as surgeons, orthopedists and laryngologists) have been able to earn 2,000 shillings a month, but this has been possible only during the last two years, since the physicians' honorariums in the insurance practice have been based on individual services. The present system works out quite favorably for the attending physician in particular cases.

The Fight Against Disease

Not long ago the new director of Vienna University's Institute of Hygiene, Prof. Dr. Max Eugling, who has been appointed to succeed the hygienist Professor Grassberger, delivered an inaugural address which had as its theme the fight against disease throughout the ages. Professor Eugling indicated that systematic care of the body (hygiene) is the best weapon with which to combat disease and that this fact was known to the ancient Greeks. In Rome six centuries before Christ, the first regularly planned drainage system was constructed and the public baths would accommodate 5,000 visitors. With the destruction of the Roman Empire in the West by the Germanic invaders the institution of the public baths fell into disuse. The Crusades brought into Europe from the Orient a formidable dissemination of contagious diseases, of which leprosy and bubonic plague are examples. At the close of the fourteenth century there were in France alone some 1,500 leprosariums. Even today there are 1,500,000 lepers among the world's population. But this formerly incurable disease can now be quite favorably influenced by treatment with preparations of chaulmoogra oil. Bubonic plague has an interesting history. It was always endemic in the Orient and is frequently mentioned in the Bible. Effective defenses against the plague were unknown. The closer contact between Europe and the Near East which resulted from the Crusades brought with it frequent opportunities for a dissemination of the contagion. The pest came to assume more and more formidable proportions in Europe. Finally, during the years from 1347 to 1350 western Europe experienced a pandemic of plague (the black death) which took the lives of some 25,000,000 persons, a good third of the entire European population of that time. Thereafter as the pest flared up again and again in particular towns it became customary to boycott and virtually isolate the stricken community, a policy that no doubt prevented a recurrence of catastrophes like the black death. Yet in the course of the last three decades 11,000,000 inhabitants of India have succumbed to the pest. Nowadays excellent results are obtained by a combination of prophylactic procedures such as disinfection of laundry by hot steam, a most reliable measure. Some of the more notable landmarks in the history of the war on disease have been the addition of quinine and the arsenicals to the therapeutic armamentarium against malaria and trypanosomiasis, and the discovery of diphtheria serum by Behring and of arsphenamine by Ehrlich. The introduction of routine antitetanic inoculation of men whose wounds had come in contact with the soil proved a prophylactic measure of tremendous importance during the World War. Throughout the conflict tetanus, once so dreaded in war, remained almost without significance. The best protective inoculation known to man is that against smallpox devised by the English physician Edward Jenner. Smallpox vaccination was first practiced on a large scale in Vienna. It might be added that all types of variola have as good as died out in those European countries in which vaccination is compulsory. The younger generation of doctors in Austria, for example, have never seen a case of genuine smallpox. In conclusion Professor Eugling said that the importance of hygiene cannot be overestimated. Just as formerly the consumption of soap within a country was considered a good indication of that nation's culture or lack of culture so today the amount of contagious disease within a country may be taken as a similar criterion.

Protection Against Diphtheria

The minister of the interior made public, October 2, new guiding principles relative to active protective inoculation against diphtheria. The author states that in the antidiphtheria campaign which has been conducted for many years throughout Germany the procedure that has proved most effective is inoculation. In the future, too, this measure will be relied on whenever an outbreak of diphtheria threatens. However, now as before, voluntary inoculation of large groups of children may be undertaken only with the permission of the ministry of labor. The serum should be injected subcutaneously either into the skin below the clavicle or into the upper part of the arm about on the insertion of the deltoid muscle. No child who has been excused from smallpox vaccination should be submitted to antidiphtheritic inoculation. Dosage should conform to the following prescriptions: If serum that contains 30 protective units per cubic centimeter is used, infants should receive injections of 0.5 cc. and children of school age doses of 0.3 cc. If the serum used contains less than 30 units but more than 10 units per cubic centimeter, infants should receive 1 cc. at each injection, children of school age 0.5 cc. (The dosage should be reduced for debilitated children and children who have already had diphtheria.) To obtain a sufficiently permanent and satisfactory immunization, inoculation with serum of the same strength should be repeated not less than four weeks after the initial injection. If a serum containing from 1 to 10 protective units per cubic centimeter is used, three injections are necessary, each to contain for infants 1 cc. and for children of school age 0.5 cc. The same type of serum ought to be used at all inoculations and the intervals between injections should be of at least four weeks' duration. The foregoing doses have been observed thus far to be well tolerated and no untoward incidents worthy of mention have been reported. If in exceptional instances a severe, medically authenticated reaction should be manifested, repetition of the inoculation is contraindicated.

Pneumothorax in Pulmonary Tuberculosis

At the Woman's Tuberculosis Center of the General Hospital in Hamburg Eppendorf, which institution serves as the university clinic, 298 patients underwent treatment with pneumothorax from 1923 to 1933. Dr. C. Mumme, head physician of the center, who recently reported his observations, has noted latterly a greater utilization of active therapy in pulmonary tuberculosis. In a general hospital, as contrasted with a sanatorium, the tuberculous patients will, for the most part, present the disease in an advanced stage unsuitable for collapse therapy. In 302 performances of pneumothorax and 4,358 refilling operations not one serious complication, such as embolism or fatal hemorrhage, occurred. If an artificial pneumothorax was complicated by a spontaneous pneumothorax (and this is more likely to occur in bilateral than in unilateral pneumothorax) the valvular pneumothorax was already closed if the air was drawn off with the refilling apparatus. Indeed, this was accomplished more quickly if several hundred cubic centimeters of air was removed from the artificial pneumothorax of the opposite side. In fifty-three cases there was a sinus exudate, in fifty cases a moderate exudate and in five cases an exudate so copious that puncture became necessary. During the last three years of the period studied bilateral pneumothorax was performed in thirty-eight cases and these interventions were much better tolerated than the unilateral. Even in an apparently high grade bilateral collapse (one which, according to the roentgenogram involved one fourth of the volume of both lungs) no injury appeared for, although the total capacity was markedly diminished, the residual air and the normal capacity underwent only

slight reduction. Favorable results were obtained even in some cases of severe cavernous pulmonary tuberculosis accompanied by laryngeal tuberculosis. Pneumothorax ought therefore to be attempted even in apparently hopeless cases, provided the disease is not yet present outside the organs of respiration.

Studies of Otitis Media and Eustachitis

Dr. Zollner of the ear clinic at the University of Jena has utilized on a large scale a new diagnostic technic in otitis media and eustachitis. He has found that the permeability of the tuba auditiva can be evaluated by microscopic observation of the membrana tympani. This procedure has elucidated the heretofore vague concepts of "tubal catarrh." The disease conditions loosely classified under this heading run a course marked by similar manifestations, but Zollner by means of precise observation has been able to subdivide these disorders into separate entities that are of disparate etiology and therefore require varied therapy. A genuine catarrhal inflammation of the tuba auditiva or of the middle ear may always be recognized by alterations in the membrana tympani, such as wrinkling, atony and changes in color. Permeability of the tuba auditiva may be badly impaired or may be normal. Actual constriction or occlusion of the tube is rare. In only a few cases is there a question of permanent cicatricial stenosis or stenosis from tumors. A third and not yet sufficiently well understood group of disorders is probably based on alterations of the middle ear. The tubes are in such cases usually permeable. Massage of the membrana tympani will improve the hearing. Still another group of patients present a pathologic dilatation of the tuba auditiva instead of a constriction. This condition is easily overlooked on superficial examination but may be detected with certainty by microscopic studies of the respiratory movements in the membrana tympani. The therapy demanded by cases of catarrhal inflammations is predominantly directed to the nasopharynx. In severe stenosis complicated surgical measures may be necessary, even a direct bouginage through the nasopharynx. Zollner was able to remove a complete bilateral occlusion of the nasopharynx by a plastic operation. In abnormal dilatation of the tube, stimulation therapy directed to the mucosa or a plastic constriction is indicated.

Acute Anterior Poliomyelitis in Apes

At Cologne in 1934 two cases of acute anterior poliomyelitis in chimpanzees were reported. Recently another case of a chimpanzee suffering from spontaneous infection with the same disease was reported also at Cologne. The minister of the interior has ordered that anthropoid apes in the zoological gardens should be closely observed for possible signs of the disease.

BUENOS AIRES

New Building for Medical School

The cornerstone for the new building of the Faculty of Medicine of Buenos Aires was laid August 9 during memorable ceremonies. The president of the country, the cardinal archbishop and delegates from Bolivia, Chile, Paraguay and Uruguay were present. The new building will cover an area of 132,500 square meters and will be constructed in a large block. The cost of construction is estimated at 16,000,000 Argentine pesos (\$8,000,000). The center of the building will be occupied by a library of 500,000 books with a reading room for 1,000 students. The school of medicine will be located in that part of the building. It will be a four-story building with a quarter for directors and a quarter for teaching histology and microbiology and a quarter for teaching anatomy. It will be located near

the front part of the building. The classes in the faculty were increased during the last year from six to twenty. The school of pharmacy will be a nine-story building at a lateral front part of the building. It will have teaching rooms and museum. Teaching rooms of topographic and descriptive anatomy and operative medicine will be located in the other lateral front part of the building. The department will have a museum of anatomy 1,850 square meters in size. There will be a large assembly hall with room for 1,000 persons, special teaching rooms for each class, and wardrobes for 4,000 medical students.

New building of Faculty of Medicine of Buenos Aires

3,000 students of dentistry and 1,000 students of pharmacy. The basement will be commodious, with parking space for automobiles and elevators for each of the different departments. The work of construction will begin before the end of the present year. Dr. Jose Arce, the dean of the faculty gave orders to demolish the building which is now the faculty of medicine and which occupied the fourth part of a block. The building will be entirely demolished in November of this year. Near the building a hospital for clinical work will be constructed. It will have 2,000 beds.

Marriages

- CHARLES OTTO REINHARDT, Mascoutah, Ill., to Miss Agnes Potasik of Lincoln, in Chicago, September 18.
EDWIN R. TALBOT, Joliet, Ill., to Miss Dorothy Constance Hoyt at Miami Beach, Fla., October 15.
CLYDE MALVERN STUTZMAN JR. to Miss Emily Albright, both of Williamsport, Pa., September 25.
SAMUEL LOGAN STEPHENSON JR. to Miss Dorothy D. Comp-ton, both of Fairfield, Ala., October 30.
WILLIAM ROBERTS TYSON to Miss Elizabeth Gertrude Ehringhaus, both of Norfolk, Va., October 4.
CHARLES MAXWELL COE, Wakefield, Neb., to Miss Miriam Hobson of Carson, Iowa, October 31.
JOHN B. TOBIAS, Wilkes Barre, Pa., to Mrs. Katherine Morgan of Scranton, September 15.
JAMES DANIEL ROYSTER, Elm City, N. C., to Miss Virginia Dean in Halifax, Va., August 16.
EDGAR WALTER STEPHENS JR., Atlanta, Ga., to Miss Ida Lee Mattison of Augusta, October 15.
EDWARD S. MALONEY, Omaha, to Miss Genevieve Mills of Santa Rosa, Calif., October 28.
HUGH WEST Deland, Fla., to Miss Elizabeth Ann Rhett Davidson, N. C., October 9.
PHILIP NATANOFF, Pittsburgh, to Miss Esther Zuckerman of Durham, N. C., August 21.
MELVIN REESF. GUTTMAN to Miss Eleanor Given, both of Chicago, December 5.

Deaths

Blase Cole * Newton, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1907, in 1937 member of the House of Delegates of the American Medical Association member of the Court of Errors and Appeals, formerly state senator, served during the World War, bank president, on the staff of the Newton Memorial Hospital aged 57, died, September 30, of injuries received in an automobile accident

William Preston Holt Jr, Erwin, N C, Jefferson Medical College of Philadelphia, 1926, member of the Medical Society of the State of North Carolina and the Southeastern Surgical Congress past president of the Harnett County Medical Society, aged 36, on the staff of the Good Hope Hospital, where he died, October 7, of an injury received in a fall

George Crarer McIntyre, Toronto, Ont Canada University of Toronto Faculty of Medicine, 1915 fellow of the American College of Surgeons, served with the Canadian Army during the World War, formerly junior demonstrator in clinical surgery at his alma mater, on the staff of the Toronto General Hospital, aged 52, died, September 27

Raymond Spear * Medical Director, Captain U S Navy, retired, Coronado, Calif Jefferson Medical College of Philadelphia, 1895 fellow of the American College of Surgeons entered the navy in 1897 and retired in 1930 for incapacity resulting from an incident of the service aged 64 died, September 28, of chronic myocarditis

Nehemiah Irving Stebbins, Nashville Ark, University Medical College of Kansas City, Mo, 1904 member of the Arkansas Medical Society formerly professor of operative gynecology at the St Louis College of Physicians and Surgeons, on the staff of the Nashville Hospital aged 68 died, September 21

Ernest Lee Cox, Jacksonville, N C, University of Maryland School of Medicine, Baltimore, 1889, member of the Medical Society of the State of North Carolina, past president and secretary of the Onslow County Medical Society, formerly county health officer, aged 72, died, September 17, of chronic myocarditis

William Neuss, Yaphank, N Y Bellevue Hospital Medical College, New York 1889 member of the Medical Society of the State of New York served during the World War aged 71 on the staff of the Swedish Hospital Brooklyn, where he died September 22, of empyema of the gallbladder and bronchopneumonia

Frederick Otis Morse, Newburyport, Mass Tufts College Medical School, Boston 1897 member of the Massachusetts Medical Society for many years examiner for the Metropolitan Life Insurance Company aged 77 died September 22 in the Anna Jacques Hospital, of cerebral hemorrhage and hypostatic pneumonia

George Cullen, Galveston, Texas Northwestern University Medical School Chicago, 1900 medical director of the American National Insurance Company formerly medical director of the Illinois Life Insurance Company, aged 62, died, September 4 of angina pectoris, near Bay St Louis, Miss, en route to Florida

Gibbs Chisholm * Newark, N J Howard University College of Medicine Washington D C, 1919, served as examining physician in the child hygiene division of the city health department, aged 45 died September 17, in the Community Hospital, of Addison's disease and pulmonary tuberculosis

Olafur Bjornson, Winnipeg Manit Canada Manitoba Medical College Winnipeg 1897, professor emeritus of obstetrics at his alma mater fellow of the American College of Surgeons, aged 67, died, October 3 in the Winnipeg General Hospital of carcinoma of the descending colon

Harold Boyce Markham, Marquette Mich University of Michigan Homeopathic Medical School Ann Arbor 1912 member of the Michigan State Medical Society formerly connected with the U S Public Health Service aged 52 died, September 22, of pneumonia

Francis Eugene Salley, Lancaster, S C Medical College of the State of South Carolina Charleston 1935 member of the South Carolina Medical Association aged 29 died September 23, in a hospital at Charlotte, N C of injuries received in an automobile accident

Joseph J Anthony Ryan Chatham N J Georgetown University School of Medicine Washington D C 1934 member of the Medical Society of New Jersey aged 33 died September 25 in St Michael's Hospital Newark of pulmonary tuberculosis

George T Cranford, Seminary, Miss, Memphis (Tenn) Hospital Medical College, 1898, member of the Mississippi State Medical Association, formerly county health officer, aged 60 died September 30, in the Methodist Hospital, Hattiesburg, of pneumonia

Warren D Wellman, Jamestown, N Y Eclectic Medical Institute Cincinnati, 1881 past president of the Chautauqua County Medical Society, on the staff of the Jamestown General Hospital, aged 82, died, September 18, of carcinoma of the rectum

Louis Josiah Leech * West Branch, Iowa State University of Iowa College of Medicine Iowa City, 1881 Civil War veteran aged 91 died, September 23 in the Methodist Hospital, Madison, Wis, of arteriosclerosis and fracture of the femur

John S Zimmermann, Youngstown, Ohio Western Reserve University Medical Department, Cleveland 1895 formerly member of the city board of health aged 73 on the staff of the Youngstown Hospital where he died, September 23

William Everett Quin, Fort Payne, Ala, Kentucky School of Medicine, Louisville 1881, member of the Medical Association of the State of Alabama, formerly secretary of the De Kalb County Medical Society, aged 86 died, September 17

Mabel T Bell, Ventura, Calif, College of Physicians and Surgeons of San Francisco, 1920 member of the California Medical Association, medical director of the Ventura School for Girls, aged 57, died, September 27, of myocarditis

Felix Marcus Tully Tankersley * Montgomery, Ala Tulane University of Louisiana School of Medicine New Orleans, 1923, served during the World War aged 39 died, September 22, following an operation for appendicitis

Samuel McChesney Ryburn, Morristown, Tenn Hospital College of Medicine, Louisville Ky, 1905 member of the Tennessee State Medical Association on the staff of the Morristown General Hospital aged 60 died, September 22

Oscar Francis Broman * Greeley, Colo Grand Rapids (Mich) Medical College, 1903, served during the World War, past president of the Weld County Medical Society, aged 62, died September 5, of acute intestinal obstruction

Edwin Melville Adams * Gridley, Ill, Barnes Medical College, St Louis, 1901, aged 60, on the staffs of St Joseph Hospital and the Mennonite Hospital, Bloomington, where he died September 26, of cerebral hemorrhage

William John Malcolm Armstrong, Mitchell Ont, Canada University of Toronto Faculty of Medicine Toronto Ont Canada, 1889 Bellevue Hospital Medical College, New York, 1889 aged 79 died September 14

George Thompson, Norwich Conn, Medical School of Maine Portland, 1889, member of the Connecticut State Medical Society aged 76 died September 17, of trauma by fall, fractured left hip and bronchopneumonia

Harvey Hay Bemis, Detroit, Detroit College of Medicine and Surgery, 1921, professor of physical diagnosis Wayne University College of Medicine, aged 41 died, October 7, of essential hypertension and myocarditis

Francis Patrick McKenna, Boston, Harvard University Medical School Boston, 1892, member of the Massachusetts Medical Society, aged 69, died, September 11, of arteriosclerosis and cerebral hemorrhage

David Barringer Phillips * Youngstown, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910 served during the World War, aged 58, died, September 22, in Phoenix, Ariz

John Sherwood McBride, Ansley, La Louisville (Ky) Medical College 1886, past president of the Jackson-Lincoln-Bi-Parish Medical Society, aged 77, died, September 13, in the Methodist Hospital, Alexandria

Arthur Edward Brides * Stoughton Mass University of North Carolina School of Medicine Chapel Hill, N C, 1910 served during the World War, aged 52 was found dead in bed, September 25 of heart disease

John A Newcome Vandergrift Pa Western Pennsylvania Medical College Pittsburgh 1892 member of the Medical Society of the State of Pennsylvania aged 72 was found dead in his office September 23

Henry Sisson Cooper, Denver, University of Colorado School of Medicine Denver 1914 member of the Colorado State Medical Society aged 46 died, October 15, in Nuda, of cerebral hemorrhage

John William Summers, Walla Walla Wash Kentucky School of Medicine Louisville 1892 served at various times as a member of Congress aged 67 died September 25 of cerebral hemorrhage

Onofrio La Raja, Scranton, Pa., Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1905, aged 56, died, September 24, in the Retreat Home and Hospital, Retreat, of arteriosclerosis

Duncan U. Saunders, Eloise, Mich., Detroit College of Medicine, 1906, assistant superintendent of the Eloise Hospital, aged 63, died, September 25, of injuries received when struck by an automobile

Weston Olin Smith, Alameda, Calif., University of California Medical Department, San Francisco, 1891, past president of the city board of health, aged 69, died, September 20, in a local sanatorium

Charles Alsop De Witt Jr., Louisville, Ky., University of Louisville School of Medicine, 1930, aged 32, died, September 24, in the Vermillion County Hospital, Clinton, Ind., of pneumonia

George P. A. Gunther, Boston, University of Pennsylvania Department of Medicine, Philadelphia, 1894, aged 84, died, September 5, in Westborough, of coronary sclerosis and chronic nephritis

James Joline Reed, Pasadena, Calif., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888, aged 77, died, September 22, of chronic myocarditis

Robert Putnam Goodkind, Boston, Harvard University Medical School, Boston, 1929, aged 34, died, September 3, in the Massachusetts General Hospital, of subacute bacterial endocarditis

William Thomas Dempsey, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1905, aged 67, died, October 19, of chronic interstitial nephritis and uremia

George W. Ragan, Cold Spring, Ky., University of Louisville Medical Department, 1891, state senator, for many years bank president, aged 72, died, September 27, of heart disease

Gilman Wayne Stauffer, Akron, Ohio, Ohio Medical University, Columbus, 1901, formerly on the staff of the City Hospital, aged 61, died, September 18, of cerebral hemorrhage

Albert S. Reiter, Myerstown, Pa., College of Physicians and Surgeons, Baltimore, 1882, aged 79, died, September 1, in the Good Samaritan Hospital, Lebanon, of arteriosclerosis

Ulysses S. Grant Arnold, Martinsburg, Mo., Washington University School of Medicine, St. Louis, 1896, aged 72, died, September 19, in Rochester, Minn., of adenomatous goiter

Joel Buford Scholl, Jabez, Ky., Louisville Medical College, 1893, member of the Kentucky State Medical Association, formerly county health officer, aged 70, died, September 4

Lewis Ryans, Louisville, Ky., University of Louisville Medical Department, 1904, formerly state senator, aged 66, died, September 26, of arteriosclerosis and endocarditis

Jesse McCampbell Reed, Magnolia Springs, Ala., University of Alabama School of Medicine, Mobile, 1914, served during the World War, aged 47, died, September 21

Alvah Clayton Bridges, Kahoka, Mo., St. Louis College of Physicians and Surgeons, 1899, also a druggist, aged 67, died, September 5, of cardiovascular degeneration

Charles Edward Davis, Cassopolis, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1874, aged 93, died, September 28, of influenza

John W. Sitton, Alvarado, Texas (licensed in Texas, under the Act of 1907), owner of a hospital bearing his name, aged 70, died, September 20, of angina pectoris

Herman Isaac Edward Blackmon, Fort Worth, Texas, Meharry Medical College, Nashville, Tenn., 1932, aged 36, was found dead, October 1, of cerebral hemorrhage

William Mead Sams, Kansas City, Mo., Kansas City Medical College, 1896, aged 71, died, in September, at the Kansas City General Hospital, of coronary thrombosis

Emma Eliza Bower, Ann Arbor, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1883, aged 87, died, October 11, of cerebral hemorrhage

William Meade Eggleston, Vicksburg, Miss., Washington University School of Medicine, Baltimore, 1875, aged 81, died, September 19, of malignancy of the pancreas

Joseph Ewing Cowperthwaite, Butte, Mont., Chicago Homeopathic Medical College, 1896, aged 64, died, September 15, of coronary occlusion and arteriosclerosis

Simon P. Berns, Willow Hill, Ill., Missouri Medical College, St. Louis, 1881, aged 78, died, September 24

Joseph K. Baker, Mooresburg, Tenn. (licensed in Tennessee in 1913), aged 68, died, September 20

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Diaplex—H W Pierce Denver Composition Essentially plant material (not named) largely stems with a small proportion of saltbush. Fraudulently represented as a safe substitute for insulin in diabetes.—[N J 25838 January 1937]

Hem Roid—Dr Leonhardt Co Buffalo N Y Composition Essentially extracts of plant drugs including aloe and nuc vomica a small amount of witch hazel was found in one sample. Fraudulently represented as a remedy for piles.—[N J 25839 January 1937]

Adams Vapour Ointment—Adams Paper & Specialties Co, Waterloo Iowa Composition Essentially menthol camphor rosin and petrolatum. For asthma catarrh croup boils etc. Fraudulent therapeutic claims.—[N J 25840 January 1937]

Adams Menthol Salve—Adams Paper & Specialties Co Waterloo Iowa Composition Essentially menthol rosin and petrolatum. For nervous headaches muscular rheumatism nasal catarrh etc. Fraudulent therapeutic claims.—[N J 25840 January 1937]

Adams Pain Ointment—Adams Paper & Specialties Co Waterloo Iowa Composition Essentially the oils of petroleum pine needles and sassafras. Fraudulent therapeutic claims.—[N J 25840 January 1937]

Gowans Preparation—Gowans Chemical Co Baltimore Composition Essentially volatile oils including wintergreen camphor eucalypt menthol and turpentine with carbolic acid in a fatty base such as lard. For pleurisy spasmodic croup pneumonia etc. Fraudulent therapeutic claims.—[N J 25842 January 1937]

B L & K R—B L & K R Medicine Co North Chattanooga Tenn Composition Essentially epsom salt extracts of plant drugs alcohol (4 per cent) salicylic acid (0.2 per cent) and water wintergreen flavored. For sore stomach heart disturbances etc. Fraudulent therapeutic claims.—[N J 25843 January 1937]

Alkavls—Williams Mfg Co Cleveland Composition Saltpeter salicylic acid an extract of a plant drug glycerin and water. For rheumatism kidney liver and blood disorders. Fraudulent therapeutic claims.—[N J 25844 January 1937]

Alcohol Rub—Fallis Inc New York Composition In one lot essentially alcohol (2 per cent) water small proportions of glycerin formaldehyde and perfume in another lot essentially isopropyl alcohol (2.1 per cent) and water. Misbranded because of false and misleading representation that the stuff consisted essentially of alcohol whereas it was largely water and because of the claim that it was endorsed by the medical profession whereas the medical profession as a whole had not endorsed the product.—[N J 25845 January 1937]

Carbolil—McKesson Berly Martin Co Nashville Tenn Composition Essentially chloral hydrate (9.5 grains per ounce) and tar oil in an ointment base largely petrolatum. Fraudulently represented as a remedy for boils skin disorders etc.—[N J 25847 January 1937]

Novo Iodine Compound—Union Products Co New York False and misleading representations that it was an iodine compound whereas it was a mixture of chloramine and potassium iodate.—[N J 25848 January 1937]

Kopp's Alcohol—C Robert Kopp Inc York Pa Composition Morphine sulfate (1/4 grain per fluid ounce) flavoring oils including anise oil with alcohol sugar and water. Fraudulently represented as a safe and proper medicine for infants and young children.—[N J 25849 January 1937]

Slim—Forest Hill Pharmaceutical Co East Cleveland Ohio Composition Capsules each containing 1 grain of dimorphinol in milk sugar. Fraudulently represented as a safe treatment for obesity.—[N J 25850 January 1937]

Eucaline (Regular)—Eucaline Medicine Co Dallas Texas Composition Essentially quinine and cinchonidine alkaloids (4.58 grains per fluid ounce) iron chloride an extract of a laxative plant drug eucalyptus oil and a small amount of alcohol with sugars and water. For malaria chills fever etc. Fraudulent therapeutic claims.—[N J 26119 February 1937]

Hawley's Ointment—Ancent Laboratories Texarkana Texas Composition Essentially lanolin camphor and boric acid. Fraudulently represented to prevent influenza and to be a remedy for catarrh hay fever croup etc.—[N J 26170 February 1937]

Melatal—Melatal Laboratories Oakland Calif Composition Essentially a crude oil. Fraudulently represented as a remedy for diabetes stomach and kidney disorders etc.—[N J 26171 February 1937]

Dabon Brushless Modern Shaving Cream—Dostane Products Corp Brooklyn Composition Essentially stearic acid potassium stearate and unsaponifiable matter emulsified with a large proportion of water. Fraudulently represented as an antiseptic and a healing agent.—[N J 26171 February 1937]

Zann Itc—Richard I Morgan Toppemish Wash Composition A light brown clay containing 13.5 per cent of water 51 per cent of silica and 20 per cent of aluminum and iron oxides with traces of calcium magnesium and carbonates. Fraudulently represented to cure diabetes gout rheumatism heart kidney and stomach disorders, etc.—[N J 26128 February 1937]

Mims (J H) Iron Tonic—J H Mims Medicine Co Jacksonville Fla Composition A watery solution of iron with sulfuric hydrochloric and tartaric acids colored with a red dye. Fraudulently represented as a remedy for indigestion dropsy eczema rheumatism pellagra etc.—[N J 26132 February 1937]

Browns (Dr) Baby Oil—Dostane Products Corp Brooklyn Composition A neutral mixture of mineral and fatty oils with a small amount of thymol. Fraudulently represented as an antiseptic and germicide.—[N J 26174 February 1937]

Sys Tone—Manufacturer not named Composition Essentially phosphorus compounds and calcium salts strychnine benzoic acid alcohol sugar and water. Fraudulently represented as a remedy for tuberculosis asthma anemia blood glandular and tissue disorders etc.—[N J 26138 February 1937]

Stocks Nu Tone Tonic—Manufacturer not named Composition Essentially extracts of plant drugs including a laxative with alcohol water salicylic acid and small amounts of sodium and calcium carbonates. For kidney liver and stomach disorders rheumatism etc. Fraudulent therapeutic claims.—[N J 26138 February 1937]

DeWitt's Cough Syrup—Manufacturer not named Composition Essentially ammonium chloride chloroform alcohol sugar and water. Fraudulent therapeutic claims.—[N J 26138 February 1937]

DeWitt's Vaporizing Balm—Manufacturer not named Composition Essentially volatile oils including menthol eucalyptol and camphor in petrolatum. Fraudulently represented as a remedy for hay fever nasal catarrh headache inflammations etc.—[N J 26138 February 1937]

Red Cross Headache and Neuralgia Remedy—Manufacturer not named Composition Essentially salicylic acid acetates common salt and water. Fraudulent therapeutic claims.—[N J 26138 February 1937]

Bi Sarcol—Bi Sarcol Laboratories New York Composition Essentially extracts of plant drugs including licorice with small amounts of inorganic compounds such as magnesium and calcium and 96 per cent of water. Fraudulently represented as increasing the red corpuscles stimulating the digestive juices toning the kidneys etc.—[N J 26140 February 1937]

Bees Laxative Cough Syrup—Manufacturer not named Composition Essentially ammonium chloride sugar and water. Fraudulent therapeutic claims.—[N J 26138 February 1937]

Nevah Tablets—Nevah Laboratories Lock Haven Pa Composition Aminopyrine (16 grains) sodium salicylate (28 grains) colchicin magnesium oxide pumice and starch. For pains of rheumatic fever gout neuritis etc. Fraudulent therapeutic claims.—[N J 26151 February 1937]

Diatone—Diabetic Diatone Inc Chicago Composition Essentially a starch digestant such as pancreatin with salt and clay. Fraudulently represented as a remedy for diabetes.—[N J 26154 February 1937]

Kirby's Miracle Mineral—Kirby's Mineral Products Union S C Composition A solution of iron sulfate in water. Fraudulently represented as a remedy for venereal diseases female disorders pyorrhea, etc.—[N J 26155 February 1937]

APCO No 36 Antiseptic Suppositories—Ampere Products Co West Orange N J Composition Gelatin capsules containing essentially boric acid quinine sulfate and cocoa butter. For feminine hygiene leukorrhea etc. Fraudulent therapeutic claims.—[N J 26166 February 1937]

Old Indian Herb Laxative—Pearson Remedy Co Burlington N C Composition Essentially extracts of plant drugs including aloe with alcohol and water. Fraudulently represented as a tonic blood purifier and a remedy for babies as well as for eczema female troubles gallstones pellagra etc.—[N J 26477 May 1937]

Videx—Grove Laboratories Inc St Louis Composition Essentially aminopyrine (2.6 grains per tablet) and starch. Fraudulently represented as a remedy for menstrual pains neuralgia rheumatism etc.—[N J 26169 February 1937 and N J 26489 May 1937]

M Edouard's B Acidophilus Compound—Z Hubay Memphis Tenn Composition Essentially a moldy mixture of agar psyllium seed milk sugar starchy material and phenolphthalein (about 28 per cent). No significant amount of acidophilus kelp or dextrin present. Fraudulently represented to contain no purgative whereas it did contain phenolphthalein and to change the intestinal flora and re-mineralize the body and furnish that unbroken chain of vitamins which is so necessary to perfect health.—[N J 26159 February 1937]

Correspondence

"RELATION OF NICOTINIC ACID TO HUMAN PELLAGRA"

To the Editor—May I call your attention to an error which occurred in THE JOURNAL, October 9, page 1203, in an editorial comment on "Relation of Nicotinic Acid to Human Pellagra." The statement referred to is as follows: "Chittenden and Underhill using diets similar to those associated with human pellagra were able to produce experimental black-tongue in dogs. They demonstrated that this disease was similar to, if not identical with, human pellagra. Conditions were thus provided for assaying experimentally the various fractions obtained during efforts to concentrate and identify the antipellagra dietary factor."

Reference to the original publications by Chittenden and Underhill and Underhill and Mendel shows that they produced a black-tongue in dogs on a diet containing an abundance of red meat and yeast. Both of these substances will prevent and cure pellagra and the Goldberger type of black-tongue. There have been no assays on pellagra curative material using this Underhill-Mendel type of diet. All the assays in the literature on the pellagra curative factor in black-tongue dogs have been done with the Goldberger type of black-tongue, which was not referred to in your editorial.

In the *Journal of Nutrition*, October 10, in an article entitled "On the Identity of the Goldberger and Underhill types of Canine Black-tongue. Secondary Fusospirochetal Infection in Each," by David T. Smith, Elbert L. Persons and Harold I. Harvey, from the Duke Medical School, it is shown that the clinical picture of black-tongue appears in both types of experimental disease but that the Underhill-Mendel type is probably due to a vitamin A deficiency, while the Goldberger type is the analogue of true pellagra in man.

In view of the great interest which is being aroused in this subject as a result of the discovery of nicotinic acid, I feel that it is important to have the background of this work clearly understood by the whole medical profession.

DAVID T. SMITH, M.D.,
Duke University, Durham, N. C.

NICOTINIC ACID AND VITAMIN B

To the Editor—In THE JOURNAL, October 9, page 1203, you had an editorial entitled "The Relation of Nicotinic Acid to Human Pellagra." It was with a sense of pleasure that I found that in describing the recent important developments in this field you referred to work of mine, carried out some twenty-five years ago, which dealt with the isolation (and the significance) of nicotinic acid, as obtained from the vitamin B complex.

Rice Polishings

Formula Given	Melting Point	Animal Experiment
I $C_6H_5ON_2$	233 C	Not tested
II $C_6H_5ON_2$ (nicotinic acid)	234 C	Not tested

You state that Funk demonstrated that nicotinic acid is a constituent of the naturally occurring vitamin B complex, even though he had apparently assigned the wrong physiologic function to this compound. This statement is incorrect and I would like to ask you kind permission to present the facts.

In 1908, when the vitamin B₁ were made during 1911-1912. The fractionation using yeast and rice polishings was repeated on a larger scale in 1912, and the results were published the following year (*J. Physiol.* 46:173, 1913). *Brit. Med. J.* 1:814 [April 19] 1913. The often repeated

statement that my curative crystalline material of 1911-1912 was merely nicotinic acid is based on an erroneous interpretation of my papers. Nicotinic acid was always found to be inactive as a cure for polyneuritis in pigeons. A summary of pertinent data dealing with the experiment carried out in 1913 will be of interest.

It itself was later found to be nothing but nicotinic acid in perfect agreement with its percentage composition, its melting point and its complete inactivity (when pigeons were used).

Yeast

Formula	Melting Point	Dosage	Activity	Survival
Crude crystalline product		4.8 mg	Cure in 2.5 hrs	46 days
I $C_6H_5ON_2$	229 C	2.8 mg	Improvement	4 days
II $C_6H_5ON_2$ (nicotinic acid)	229 C	10.00 mg	No activity	13 days
III $C_6H_5ON_2$	222 C	5 mg	No activity	0-1 day
I and II		{ I 3.5 mg } { II 2 mg }	Cure in 2.4 hrs	41 days

Even more marked curative results were obtained by combining all three fractions (I, II and III).

It is quite plain, from this summary, that the only claim made for nicotinic acid was that it enhanced the physiologic action when added to the other fraction or fractions—a point of view which is in perfect agreement with our present knowledge of the vitamin B complex. This enhanced action of nicotinic acid and nicotinamide was later confirmed by Szymanska and Funk (*Chem. Zelle u. Gewebe* 13:44, 1926) and Casimir and Jan C. Funk (*J. Biol. Chem.* 110:222 [April] 1937).

I wish to emphasize, finally, that at no time was nicotinic acid mistaken for vitamin B₁.

CASIMIR FUNK, Rueil-Malmaison, France

THE RECURRENT LARYNGEAL NERVE

To the Editor—Granted I erred, even according to the nomenclature which was my authority, in stating there is only one recurrent nerve. There are two. And Dr. Oscar A. Batson's cross tabulation (*THE JOURNAL*, November 6, p. 1562) confirms my contention that "the BNA does (not) recognize the recurrent laryngeal nerve. The nerve under consideration is so designated in the British nomenclature. I might add here that Dr. Batson's tabulation also demonstrates to me the futility of quibbling about names in view of the confusion resulting from differing terminologies. However, the BNA, being the consensus of an international congress, may be expected to be more authoritative than the classification of any national group.

A recurrent nerve is one that retraces its course in arriving at its insertion. Neither the maxillary nor the mandibular nor the many other recurrent meningeal nerves are recurrent in its anatomic connotation. Dr. Wharton Young to the contrary. An anatomic nomenclature serves the purpose of incisive description. From that standpoint "recurrent laryngeal" as there is only one (paired) recurrent nerve, is redundant and therefore ambiguous.

There is an anatomic basis for the relative infrequency of right laryngeal paralysis following thyroidectomy and that basis is explicable only in terms of embryologic development. The right inferior laryngeal or recurrent nerve (BNA) or the right recurrent laryngeal nerve (BR), in deference to Dr. Young and Batson, lies to the right of the esophagus whereas the left lies in front of it in anteroposterior relation, a difference of from 0.5 to 1 cm. in favor of the right for greater depth.

Though the editorial in question (*Total Thyroidectomy for Congestive Heart Failure*, *THE JOURNAL*, July 17, p. 210) concerned thyroidectomy primarily and laryngeal paralysis only incidentally my communication (*THE JOURNAL*, September 4, p. 809) was concerned chiefly with an anatomic explanation of

the clinical observation of the greater frequency of left laryngeal paralysis following thyroidectomy. From that standpoint it was only relatively in error and the inclusion of mediastinal disease in connection with the subject of laryngeal paralysis was more germane to it than reference to the trigeminal nerve was to the subject of recurrence—and with greater accuracy.

It follows that the editorial did not contain 'by implication a gross falsehood'—the error is mine. Nonetheless, in stating that the paralysis "in no instance was bilateral" it was shown that the anatomic basis for the clinical phenomenon was not realized. Had the paralysis been bilateral or only right sided, it would have been the more startling and of itself, been evidence of shoddy surgery.

JOHN F. QUINLAN, M.D., San Francisco

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DIFFERENTIATION OF HIP SACROILIAC AND LUMBAR LESIONS

To the Editor—Please differentiate disorders of the (1) hip joint (?) lower part of the back and (3) sacroiliac joint and the anatomic reasons for the tests. SAMUEL L. IMMERMAN, M.D., Philadelphia

ANSWER—In the differentiation of hip, sacro-iliac and lumbosacral disorders the following tests are useful but not always conclusive:

1 Point of tenderness. In hip joint disease, tenderness is commonly found anteriorly over the hip joint capsule. Sacro-iliac involvement may be associated with tenderness over the inferior sacro iliac ligaments. In lumbosacral disorders, tenderness over the interspinous and the iliolumbar ligaments may be found.

2 Mobility tests. Restricted or painful motion of the hip joint may indicate disease of this joint. Care must be taken to differentiate muscle spasm and restriction due to irritation of the sciatic nerve. Mobility of the lumbar spine is tested with the patient in the standing and sitting positions. In lumbosacral disorders the spine is held rigid in both positions while in sacro iliac disorders there may be ability to flex the spine until tightened hamstrings put stress on the sacro iliac joint. The sitting position facilitates flexion of the spine in sacro-iliac disorders.

3 Manipulative tests. These are done with the patient in recumbency. (a) Passive flexion of the two hips at the same time places the lumbosacral joint under stress. (b) The straight leg raising test places stress on the sacro iliac joint by the pull of the hamstring muscles on the ischium and may reproduce pain in this joint. It also puts tension on the sciatic nerve and a positive test may be obtained in any condition associated with irritation of that nerve or its roots. (c) The Patrick sign, obtained by flexion abduction and external rotation of the thigh stretches the anterior portion of the hip joint capsule and through it may place stress on the sacro iliac joint. It may be positive in either hip or sacro iliac joint disorders. (d) The Gaenslen test of hyperextension of one thigh with flexion of the opposite thigh places rotary strain on the sacro-iliac joint. (e) Compression of the iliac crests may occasionally reproduce sacro iliac but not lumbosacral pain.

Thorough roentgenographic study is always indicated and may assist in localizing the disorder.

STAMMERING

To the Editor—Can you advise me as to the desirability of sedative treatment in cases of stammering in young children and the way in which it should be employed? WILLIS H. MCGRAW, M.D., Cortland, N.Y.

ANSWER—Sedative treatment in stammering must, of course be purely palliative. It has ceased to be invoked in mental hygiene clinics where speech defect cases are thoroughly studied for two reasons. One is that the dosage of a sedative in a young child, no matter how small, produces untoward symptoms, and even if the drug is practically non-habit forming such as phenobarbital or bromides, the tendency is for the child

to become accustomed to it. A much more serious objection is the fact that it has not produced the results that had been hoped for. Instead, the child should be thoroughly studied as to the emotional, intellectual and physical components that might be behind such stammering, and treatment should be on the basis of psychologic function rather than on sedation. The majority of stammering cases are due to some emotional maladjustment between the child and the parents. This would have to be looked into with a mental hygiene questionnaire, and the treatment based on the cause rather than the symptoms.

CERVICITIS AND PROSTATITIS AS CAUSE OF LEG PAINS

To the Editor—A woman who had her cervix cauterized under a local anesthetic noticed immediately on leaving the table that a partial numbness existed in the left leg running down into the great toe. This became progressively worse and painful for three days and subsided as healing took place in the cervix. There was no question of pressure as the legs were not held in straps or supports. The numbness is present in varying degree even after eighteen months and is somewhat better after menstruation. The neurotic element can be excluded. A man with a badly infected prostate complained of feeling the massage all the way to his great toes. He had noticed for months that when his prostate was sore there was pain in the toes even to the point of making walking difficult. This symptom was relieved when the prostate was less sore and discharge was minimal. The presence of this symptom on massage of the prostate was confirmed by two gynecologic surgeons who had noticed the same thing. Is this reflex rare? A neurologist consulted by the first patient said he had never heard of it. Is there any suggestion for the relief of numbness and attendant cramps which she complains of if it is due to the cauterization? The pelvis is otherwise entirely normal.

M.D. Pennsylvania

ANSWER—It is difficult to conceive how cauterization of the cervix could be the cause or subsequent numbness in the leg. There is no physiologic or anatomic relationship existing in these areas. Inquiry among several gynecologists of experience fails to elicit a similar observation. It is possible that the patient was placed in such a position that pressure on one of the nerves in the leg was the cause of the pain. It is also possible that the cervix, which is frequently a focus of infection, may have been the cause of a coincidental localized neuritis.

There is also no anatomic relationship between the nerves of the prostate gland and the leg. While pain is frequently observed on vigorous massage of the prostate gland, it is extremely rare to find that the pain extends as far as the toes. The sensitive patient may complain of pain in the lower part of the abdomen, and in some cases the pain may radiate to the hips. The pain in the toes complained of by the patients referred to might be caused by a coincidental neuritis or arthritis subsequent to infection in the prostate gland. In all cases of this kind it would be well to exclude any other possible foci of infection in either teeth or tonsils. It might be advisable to try applications of heat and contrast baths for the numbness and cramps in the leg.

TREATMENT OF CHRONIC PROSTATITIS

To the Editor—A white man aged 44 married for the first time five months ago complains of aching pain in the left knee joint similar to that which he had when he first contracted gonorrhea. At that time (about twenty years ago) he was treated with vaccines and recovered with no disability. He had no epididymitis but had a stricture which was never treated. At present there is no discharge or morning drop. Massage of the prostate brings forth a cloudy whitish fluid. The prostate itself appears soft, symmetrical and not tender. A soft rubber catheter meets resistance in the anterior part of the urethra and obstruction at the membranous portion. The knee joint is not tender, red or swollen nor is there limitation of motion. The patient works in a slaughter house and frequently passes into and out of the icebox at times he even remains in it for an hour or so. Glass tests have changed the urine from cloudy to clear with a lessening in the number of shreds. Smears taken directly from the penis show gram-negative diplococci intracellular and extracellular with epithelial and pus cells. The smear taken after prostatic massage shows a similar picture. I have been using potassium permanganate solution for irrigation and 1:2000 Silvolon solution for instillations. I hesitate to sound the urethra for the stricture for fear of pushing the infection farther up. Can you suggest a procedure for getting a more rapid result? Would intercourse be safe at this stage?

M.D. New York

ANSWER—The first question to be decided is whether this patient has gonorrhea. Repeated examinations by Gram's stain and culture of any urethral discharge and of the prostatic secretion should be made to determine the presence of the gonococcus. If this organism is present, of course sexual intercourse must not be allowed. If it is not present, the condition must be treated as chronic nonspecific urethritis and prostatitis with probable stricture. The urethra should be sounded, and if stricture is found it should be dilated even though an exacerbation of symptoms is possible. A thorough search for other

foci in the teeth or tonsils should be made, and if any infection is found it should be eradicated. Then a regular course of prostatic massage, with irrigations of the urethra and bladder if necessary should be started. One should be careful not to overtreat. It is best to carry on a regular period of treatment for from ten to twelve weeks and to follow this with a rest from all treatment for a similar period. A second course of therapy may be needed. Conditions of this sort are frequently stubborn and prolonged. However, with cooperation and perseverance on the part of the physician and the patient, an eventual cure should be obtained.

FAINING

To the Editor—A woman aged 24 has had trouble with fainting spells ever since she was small. They followed excitement or undue strain. She would come home from a shopping trip and while trying on some of her new clothes would fall in a faint. There is no hysteria, she does not need an audience, neither is there any cry or foaming at the mouth or any convulsions. The patient had fairly regular periods but was given theelin before she could become pregnant. A baby was delivered spontaneously after only six hours of labor. There was considerable postpartum hemorrhage which was finally controlled. Six days later she began having chills and fever which was the beginning of a thrombophlebitis in the left iliac veins. She is still in bed. Her progress has been hampered considerably by these fainting spells which are more severe than any one has seen before. She cannot feel her lower extremities, her head feels like a vacuum. She does not lose consciousness completely. Her blood pressure and pulse remain good, neither is there any change in her temperature. Her red blood count even after considerable blood loss is four million and her hemoglobin seventy per cent. The white count was 20,000 but is only 10,000 now. The blood pressure is always low, systolic 105 diastolic 65. The patient is well developed and well nourished and in my opinion is going to recover from her present trouble. I should like to know the basis for these spells. What can be done for her? Is there a glandular dyscrasia? She seems to be normal in every other respect. The thyroid is normal at present but it did enlarge somewhat with pregnancy. Adipose tissue is distributed normally. The baby was perfect and has remained so and is bottle fed. MD Nebraska

ANSWER—Before a definite diagnosis is made in this case, a more complete series of examinations will have to be carried out. This should include a thorough investigation for the possible presence of a brain tumor and for disturbances in the eyes and ears. Hence it is important for a neurologist and otologist to study the patient. Likewise a basal metabolism study should be made and a roentgenogram of the skull taken. If all physical and laboratory examinations fail to reveal a definite cause, it must be assumed that the cause of the fainting spells is a psychic one. It this is the case a cure can be effected in most instances by a competent psychiatrist or psychanalyst.

ASTIGMATISM

To the Editor—A woman aged 35, tiredness of the eyes, blue halo along the edges of the lens. The patient contained some fine lines in the lens. The patient was normal. Examination of the fundi showed normal. The blood pressure was 135 systolic and 80 diastolic. Corrected vision gave 20/20 in each eye. A first grade colorless lens with an appropriate add for reading was prescribed. The patient returned with the new lenses and is able to see better than formerly but she still complains that she is disturbed by seeing blue above words and a yellow streak below. Also is conscious of seeing these colors when outdoor in bright sunlight. She does not have disturbed vision in reduced illumination and there are no evidences of any other illness. What may be some of the causes for this condition? What can be done to relieve? MD Indiana

ANSWER—The only condition in which a 'streak' or 'line' is seen above or below or both above and below a given word or line of either the Snellen chart at 20 feet (76 meters) or a chart used to test the near vision is uncorrected astigmatism, and patients have never spoken of any color in connection with such doubling of the line. If the blue image is an entirely separate image, astigmatism can be ruled out. If it merges with the image of the word it probably is an odd astigmatic phenomenon. Blue vision and blue lines are encountered only after

INFANTILE VACCINES

To the Editor—Is anthrax vaccine? Is Pasteur's vaccine such a rabbit, the driving cord virus and leads sample vaccine is

nervous tissue of rabbits infected with rabies the virus in the tissue having been killed completely by mixture with phenol. In this case the treatment consists entirely of the injection of killed virus.

PALLIATIVE TREATMENT OF CANCER

To the Editor—Is there anything that might be of value in palliative treatment for a patient dying with cancer of the breast aside from narcotics or the usual drugs? She has had a tremendous amount of x-ray treatment since her breast was removed one and a half years ago.

MD California

ANSWER—Unfortunately, there is no palliative treatment for advanced carcinoma which has any curative value but much can be done for such patients by judicious manipulation of drugs. For example, the administration of small doses of codeine mixed aminopyrine or acetphenetidin and acetylsalicylic acid mixed together may supplant the stronger narcotics, such as morphine or dilaudid, for a time. Each of these opium preparations seems to have a rather different effect on different patients, so that the drugs can be changed after two or three weeks to avoid habituation to one form. In fact one type of drug may prove far better than any other for a given individual. It is entirely a matter of trial.

Care should be taken to remove fluid from the chest in case it accumulates, as is probable, and small doses of x-rays often relieve bone pains and make the patient feel she is being cared for. These x-ray doses should be given not more than twice a week and should be small in amount. Care should be taken not to use the x-rays over areas in which the skin is damaged by previous irradiation, otherwise extensive ulcerations which are painful may appear. The psychic effect of interest and evident sympathy are valuable even in patients suffering from an incurable disease.

TRAUMA AND CORONARY OCCLUSION

To the Editor—A man aged 65 with a past history of active life in regular working hours tells this story. About 3 p.m. he slipped as he sat leaning in a chair and was thrown into a sharply knifed position between his chair and the wall. He had some discomfort across the lower part of his chest and complained of it several times that night. The following morning at 9 o'clock he experienced a much more squeezing type of pain under the sternum and down the left arm. He became pale and began to sweat profusely. His blood pressure dropped from 134 to 104 during the following forty-eight hours. He had a slight fever of 101.2 F, a leukocyte count of 12,000, a sedimentation time which increased in rapidity by the third day and an electrocardiogram typical of coronary occlusion. The course was uneventful, the fever disappeared within a week and the sedimentation time reached normal limits within three weeks. There was no past history suggesting coronary sclerosis. His blood pressure has been in the neighborhood of 132 systolic 80 diastolic. A competent eye man reports that there have never been any arterial changes in the retina. An examination of his peripheral arteries does not at this time reveal any evidence of sclerosis. I would appreciate an opinion as to whether trauma in this case or any other cases might be considered as an etiologic agent in the production of the thrombosis. MD California

ANSWER—From point of time it does seem as if the coronary thrombosis that developed in this patient was definitely related to the injury. Such relationship cannot ordinarily be established. Coronary thrombosis usually comes out of a clear sky, but there are instances in which injury and strain possibly have helped to precipitate coronary thrombosis in a vessel already badly damaged perhaps through rupture or dissection of the wall or of a "cholesterol abscess" or of a sclerotic plaque. There are not, however enough data as yet to make any clear statements about such a relationship.

RENAL CALCULI AND NEPHRITIS

To the Editor—In one of two patients with renal calculi lying in the pelvis of the kidney there was renal colic and in the other no colic. In the heavy albuminuria without (macroscopic) pyuria. In the latter the calculus was removed by operation and the albuminuria soon ceased. In the former there was macroscopic pyuria but an amount of albumin of only one-fifth of all proportion to the amount of pus. Neither showed any signs of diffuse nephritis such as edema, hypertension, vascular changes or retention. What is the pathologic physiology of the albuminuria in these cases? I have difficulty in seeing how glomerular function can be influenced by a calculus in the kidney pelvis accepting the fact that protein in such large quantities must escape by way of the glomerular epithelium. MD Florida

ANSWER—Albumin is frequently found in large quantities in the urine as a result of renal stone. This may be caused by red blood cells, pus cells or a mucopurulent exudate resulting from secondary irritation in the surrounding renal tissue. These elements usually disappear from the urine following removal of the stone, although they may be present in diminishing degree for a period of several months to a year. It is hardly to be expected that there would be any clinical evidence

diffuse nephritis, renal insufficiency or vascular changes in the presence of a presumably normal kidney on the other side. In fact, even though renal calculus is present in a solitary kidney, it is seldom that evidence of diffuse nephritis or renal insufficiency results unless there is very extensive destruction of renal tissue. Glomerular functions are undoubtedly influenced by calculus in the kidney, as shown by reflex inhibition of excretion of dye. This may be graphically visualized in the excretory urogram, where a renal calculus often will cause failure of visualization following intravenous injection of solutions of iodine used for urographic purposes. Tests of renal function made by means of dyes such as indigo carmine, when calculus is present, reveal a lessened intensity or the dye return or complete absence. Within a few days after removal of the calculus the function of the kidney will usually be restored to normal, as shown by normal visualization in the excretory urogram. Since it has been shown that the excretion of urographic mediums is largely a glomerular function, it is evident that the glomeruli are directly involved in reflex inhibition of excretion.

PROGRESSIVE MUSCULAR ATROPHY OR LEAD POISONING

To the Editor—A man aged 58 for the past fifteen years has been employed in a jewelers supply shop. During this time his sole job has been to file solder from the joints of rough gold brass plates. He states he has noticed progressive loss of strength in the hands and arms for a year. Several years ago he had frequent severe headaches and before that he had attacks of colic in the left lower quadrant of the abdomen which a physician told him were due to gallbladder trouble. Examination now reveals marked atrophy of the thenar and hypothenar muscles and the inter ossei and some wasting of the larger groups of both arms and forearms. The fingers of both hands are contracted into the flexed position seen in Dupuytren's contracture. There is a bilateral double wrist drop. There is constant coarse fibrillary twitching in the muscles of the arms and shoulder girdle. There is some weakness of the lower extremities and the gait is of the waddling type but there is no toe drop. There are no sensory changes either subjective or objective. The pupils are equal and regular and they react to light; the fundi are normal except for some tortuosity of the arteries. There is a double false denture. The chest is emphysematous, the lungs hyperresonant, the heart is essentially normal. The blood pressure is 180 systolic 100 diastolic. The hemoglobin is 70 per cent (Tallqvist). No lumbar puncture has been done. I feel very strongly that this is a case of chronic lead intoxication. There is no lead line owing to the false teeth. A smear of the blood showed no basophilic stippling with Wright's stain. Would x-ray examination of the long bones demonstrate the presence of lead? What is the procedure for having an analysis of the urine done? Is a how large a specimen? Assuming that he does have lead poisoning, should treatment be directed toward deleading him with iodides and acid ash diet or should he be given calcium and vitamin D?

M D Massachusetts

ANSWER—This patient's condition sounds more like progressive muscular atrophy than lead poisoning though occasionally lead poisoning may mimic the latter disease. The diagnosis of lead poisoning necessitates some other objective sign. A roentgenogram of the long bones does not demonstrate the presence of lead in an adult, it is of value in children only before the epiphyses unite. To have an adequate analysis of urine for lead, one should have at least a twenty four hour specimen. If one assumes that this man does have lead poisoning, it would be wiser to delead him with a low calcium diet, which contains no milk eggs or green vegetables. To this should be added ammonium chloride in a 20 per cent solution one teaspoonful six or eight times a day in full glasses of water. This should be continued for about six weeks, after which he should return to a high calcium diet. Iodides may be used but they do not seem to be as effective as the treatment outlined.

FIBROSIS OF PENIS FOLLOWING GONORRHEA

To the Editor—A white man aged 66 with a history of gonorrhea forty years ago has had curvature of the penis on erection for the past six months. The curvature is opposite in direction to that of the usual chordae of gonorrhea. Erection is painless. During an erection the patient is unable to straighten the penis manually. Intercourse is impossible. Ejaculations are present. Physical examination is negative. There is no stricture of the urethra. The prostate is normal. The blood pressure is 170 systolic 90 diastolic. The urine is normal. There is nocturia from three to eight times resulting from copious drinking of water. Is it possible that there has been a fascial tear or stretching of the fascia on the urethral side and would it be possible to plicate the fascia on the urethral side or cut fascia on the opposite side so as to allow the penis to be straight on erection? Are there any references?

M D New York.

ANSWER—The condition described is probably caused by a noninflammatory fibrosis involving the corpora cavernosa. It is commonly referred to in the literature as plastic induration of the penis, chronic cavernositis, circumscribed fibrosis, and La Peyronie's disease. La Peyronie gave the first full description of the lesion in 1743.

There is still a difference of opinion as to the nature of the lesion, but apparently it is due to a noninflammatory fibrosis affecting chiefly the smaller vascular sheaths in the corpora cavernosa. Multiple areas of induration are usually found in the penis, most often in the dorsal portion near the base. In some cases there are linear areas of induration which are difficult to palpate. Pathologic examination of the indurated area usually reveals elastic fibrous tissue. Deformity of the penis while in erection, similar to that described, is frequently present and is often painful. The progress of the disease is slow and after reaching a certain stage it usually remains stationary. In many cases the severity of the symptoms will gradually subside.

There is no known effective treatment for this condition. Surgical removal and plastic operations have been tried frequently and have proved unsatisfactory. Better results have been obtained from the use of radium than any other form of treatment. In some instances the plaques are considerably softened and, although they do not usually disappear, they have been so reported in a few cases. In some cases radium has been of distinct benefit in causing amelioration of pain, although the deformity is not usually affected. Patients are often made more comfortable if assured that the disease is not dangerous to life.

DEXTROSE IN SHOCK TREATMENT OF DEMENTIA PRAECOX

To the Editor—In reading the literature on insulin shock treatment for dementia praecox I find reference to a special tube feeding technic that has been devised by Dr Sakel. Will you kindly describe this technic?

M D Indiana

ANSWER—The hypoglycemic coma or shock is terminated by Sakel with a tube feeding of from 100 to 150 Gm of sugar in solution. Water, tea, milk or orange juice may be used. When it is intended to produce a prolonged shock, the tube is inserted prophylactically at the beginning of coma and its position is checked from time to time by aspiration of gastric juice and a litmus test of its acidity. Dipping the filled funnel below the level of the lung at the beginning of tube feeding will also show, by the absence of bubbles, or by holding it to the ear, that the tube is not in the trachea. Even in severe shock the sugar is quickly absorbed in the stomach. The patient begins to awaken from seven to fifteen minutes after the feeding and is usually completely awake in from half to three quarters of an hour. If vomiting occurs during a tube feeding, the patient is turned on his side and the intravenous administration of sugar is resorted to.

PSYCHOSIS AND HYPERTHYROIDISM

To the Editor—A woman aged 46 with a previous history of nervousness and neurasthenia had a thyroid crisis three years ago and a mild but definite psychosis developed. The psychosis is expressed by a negativistic and unresponsive attitude coupled with the maintaining of a fixed position in bed with the arms rigid and flexed. She hears understandings and remembers as well as any one and is slightly responsive to the questions of her husband who feeds her and attends to her needs. She has a flushed face, a warm and moist skin, eyelids that are closed and tremulous and a hard fixed adenoma of the right lobe of the thyroid. The lungs are clear, the heart rate varies between 110 and 130 and the weight curve is relatively constant. No metabolic tests, chemical tests of the blood (especially of the calcium and phosphorus) or tests of the renal functions have been performed. Can subjective and objective improvement be expected with a thyroidectomy, especially in the mental status? In general what is the mental response to a thyroidectomy in persons who have a psychosis as a result of a hyperthyroidism?

M D

ANSWER—A psychosis appearing in a patient with thyrotoxicosis may disappear with the cure of the thyrotoxicosis. The result depends on a good many factors. If the mental symptoms are entirely the result of the thyrotoxicosis, recovery may be expected but if the toxic state is only an exciting agent for an underlying psychosis, appropriate treatment will leave the patient unchanged as far as the mental symptoms are concerned. There is no definite way to differentiate between these two types of psychotic reaction for there is nothing characteristic about the mental state which is associated with, or caused

by, thyrotoxicosis. Treatment however, is usually indicated and certainly should be advocated in this case. If thyrotoxicosis is present, the patient may respond to iodine and this alone may be enough to improve the mental state. If operation is indicated by the presence of adenoma, surgical treatment should be instituted in the hope that it will affect the psychosis. The value of treatment of thyrotoxicosis in cases of mental disease is discussed on pages 433-436 of "The Thyroid and Its Diseases," by Dr J H Means, Philadelphia, J B Lippincott Company, 1937.

THYROID ADENOMA

To the Editor—A woman aged 24 has an enlargement of the right lobe of the thyroid. This enlargement is the size of an egg and is smooth, uniform and firm but not hard. At times it is more prominent especially during menstruation. There is occasional difficulty in swallowing. She is in good health with the exception of the following symptoms which I have associated with the thyroid: constant fatigue, occasional attacks of tachycardia, occasional periods of being very warm and perspiring hands. There is no perceptible tremor. This swelling was first noticed about a year ago and the patient states that it has become slightly larger. She has gained 7 pounds (3.2 Kg.) in the past two months. Her present weight is 107 pounds (48.5 kg.) and she is 64 inches (163 cm.) tall. A basal metabolic test taken March 20 showed a rate of plus 2.4 per cent. Can this type of thyroid which I have considered a simple goiter be treated with compound solution of iodine and if so what would be the proper dosage? Would it be just as well to use iodostarine giving one tablet daily for thirty days during alternate days? If the latter is recommended over how long a period should this treatment be carried out? What about surgery?

M D Illinois

ANSWER—This patient, in all probability, has an adenoma in the right lobe of the thyroid, its change in size with menstruation strengthens this belief. Pressure on the esophagus may account for the occasional occurrence of dysphagia. It is most unusual for an adenomatous goiter to cause hyperthyroidism before the age of 30, therefore the normal basal metabolic rate in this case is to be expected. However, adenomas may cause symptoms such as she has with the basal metabolic rate in normal limits. A neurosis of some type may account for the symptoms.

Malignant degeneration may occur in such an adenoma, even at her age, and the rather rapid development of the enlargement in this instance would make one suspicious of a malignant condition although the chances are against it.

Compound solution of iodine will not cause the tumor to disappear and its use is not indicated, as it has no place in the treatment of goiter except in hyperthyroidism and then only as a preparation for operation.

Iodostarine or any other iodine prophylactic may be used as a prophylactic against the occurrence of goiter during adolescence and pregnancy and as a treatment for colloid goiter with hope of success up to about the age of 24. It will not cause an adenoma of this size to disappear.

Surgical removal of the adenoma is advisable because it may be the site of malignant degeneration and will prevent the occurrence later of hyperthyroidism and cardiac damage. No other treatment will do other than temporarily influence the symptoms. Surgical treatment will in all probability cause the symptoms to disappear, in addition to being good preventive medicine.

PARATHYROID EXTRACT IN HYPERTROPHIC ARTHRITIS

To the Editor—A patient of mine with long standing chronic hypertrophic arthritis may recently about the use of parathyroid extract in her disease. Can you give me some information as to its effectiveness, dangers and contraindications together with the recommended dosage? I would appreciate it if you would give me some references that I might read.

M D Ohio

ANSWER—The use of parathyroid extracts in chronic arthritis has been discussed in some detail in *Queries and Minor Notes* (THE JOURNAL, Oct 13 1934 p 1171) and critical comments on parathyroidectomy for arthritis are included in the recent "Third Rheumatism Review" (Ann Int Med 10 754 [Dec] 1936). In order to justify the use of parathyroid extracts for arthritis one should be able to demonstrate a consistent abnormality in mineral especially in calcium metabolism in this disease but no such alterations have been found to exist. Recent and previous investigations have failed to show any significant change in the calcium content of the blood or urine or in the calcium content of the bone either with chronic infectious (atrophic) or with hypertrophic arthritis. In 97 per cent of 100 cases of atrophic and hypertrophic arthritis, Hartung and Greene found normal blood calcium values (J Lab & Clin Med 20 920 [June] 1935). These results are in agreement with the report of Buckley and Race (First Research Report of the Devonshire Hospital, Bristol, John Wright & Sons Ltd 1928) of Bauer, Bennett and Short (Brit Eng Med J

Med 208 1935 [May 18] 1933) and of Race (Reports on Chronic Rheumatic Diseases, No 1, edited by C W Buckley, New York, Macmillan Company, 1936).

The abnormalities in bone calcium seen in arthritis (bone atrophy in certain stages of atrophic or rheumatoid arthritis and marginal bone hypertrophy in hypertrophic or osteoarthritis) are believed to be due not to any general fault in calcium metabolism but to local changes in circulation. It has been shown (Jones R W, and Roberts R E Brit J Radiol 7 321 [June], 391 [July] 1934) that an increased blood supply to bone will produce atrophy, a decreased blood supply to bone will provoke hypercalcification. It is suggested that the atrophy of bone in atrophic arthritis may therefore be due to the increased (not decreased) capillary circulation which inflamed synovial membrane exhibits and that arteriosclerotic or inflammatory changes in nutrient vessels of joints may be responsible for some of the bone changes seen in hypertrophic arthritis. Part of the latter at least are probably due to inflammation in the periosteum. Parathyroid extracts have been used for arthritis empirically by a few investigators but without much success (for references see previously mentioned note). More recently some have tried to prove that the arthritic patient (with atrophic arthritis or with "ankylosing polyarthritis or spondylitis") needs not more parathyroid extract but less. It is argued that chronic arthritis is a symptom of hyperparathyroidism and that parathyroidectomy is therefore indicated. Some writers have reported that their arthritic patients have derived considerable relief from this. However, histologic examination of the tissues removed at "parathyroidectomy" by one proponent of this idea indicated that from 28 per cent of his improved patients no parathyroid tissue had actually been removed.

Those who have had the largest experience with cases of undoubted hyperparathyroidism in this country refuse to mention parathyroidectomy for arthritis or to admit that roentgenograms of patients with arthritis or with hyperparathyroidism show common pathologic alterations. It must therefore be concluded that at present there is no rationale for prescribing parathyroid extract or for removing the parathyroids from patients with either atrophic or hypertrophic arthritis.

CYSTOCELE AND BACKACHE

To the Editor—Is uterine anteversion of moderate degree together with a small cystocele of which the patient is unaware a plausible explanation for disabling backache? The degree of flexion is not sufficient to cause any dysmenorrhea.

M D Michigan

ANSWER—Anteversion is not a cause of backache. A cystocele would produce backache only in conjunction with prolapse of the uterus and relaxation of the uterine supports. Of course if there is infection of the urinary tract due to poor emptying of the bladder because of the cystocele it is possible that the backache might be caused by the focus of infection in the urinary tract.

EXERCISE AFTER NEPHRECTOMY

To the Editor—Following a nephrectomy in which there was the usual incision with the division of muscles but no infection and primary repair, what in your opinion is the length of time required before a woman might return to active sports such as golf?

M D Illinois

ANSWER—In the average noninfected case with good repair of the wound following nephrectomy, strenuous exercise such as golf should usually be withheld for a period of at least two months after healing. There are some factors, however, which may extend this interval. In case of a thick muscular or fatty abdominal wall it may be advisable to wait until a period of three months has elapsed. Subsequent muscular weakness in the wound is apt to result from accidental severing of the nerve supplying the area involved rather than from violent post-operative exercise.

AMENORRHEA WITH INFANTILISM

To the Editor—A 15 year old girl who commences have not yet started developed an acute condition of the abdomen. A strangulated right ovarian cyst was removed. It measured about 2 by 3 inches, the entire ovary and right tube were in the strangulated mass. Inoperatively it was noted that her secondary sex characteristics were poorly developed. Operation revealed a uterus little better than infantile. Would gonadotropin therapy be indicated and if so what type? If estrogen is given, will it depress the gonadotropic function of the anterior pituitary? Are there any satisfactory pituitary products available for such a case?

M D Connecticut

ANSWER—At the age this girl has reached the amenorrhea is probably due to the infantilism. Delay in treatment increases the chances that the condition may become permanent so treatment should be begun immediately. Thorough physical exami-

anion must be done in order to rule out vaginal occlusion, anemias, thyroid disease or any general debilitating disease that may be responsible for the amenorrhea. Should the examination reveal nothing abnormal, treatment with gonadotropic extract of pregnancy urine (antuitrin-S, antophysin, A P L, follutin) is indicated. This will stimulate the ovary to produce estrogen which will act directly on the uterus to increase its size and develop the endometrium, thus providing the local conditions that lead to menstruation.

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, August 28.

Hospitals Approved for Intern Training

- Norwood Hospital Birmingham Ala
- Highland Sanitarium Shreveport La
- North Louisiana Sanitarium Shreveport La
- Tri State Hospital Shreveport La
- Long Island Hospital Boston
- Providence Hospital Holyoke Mass
- St Mary's Hospital Orange N J
- St Mary's Hospital Passaic N J
- Fairview Park Hospital Cleveland
- St Joseph's Hospital Parkersburg W Va
- Presbyterian Hospital San Juan P R

Hospitals Approved for Residencies in Specialties

- Anesthetics**
 - Hartford Hospital Hartford Conn
 - St Mary's Kahler Hospitals (Mayo Foundation) Rochester Minn
 - Flower Fifth Avenue Hospital New York City
- Medicine**
 - St Luke's Hospital San Francisco
 - Massachusetts Memorial Hospital Robert Dawson Evans Department of Clinical Research and Preventive Medicine Boston
 - De Paul Hospital St Louis
- Neurology**
 - Gallinger Municipal Hospital Washington D C
- Neuropsychiatry**
 - Westboro State Hospital Westboro Mass
 - Bishop Clarkson Memorial Hospital Omaha
 - Harding Sanitarium Worthington Ohio
 - Danville State Hospital Danville Pa
- Obstetrics**
 - Geo F Geisinger Memorial Hospital Danville Pa
- Obstetrics Gynecology**
 - Curney Hospital Boston
 - Flower Fifth Avenue Hospital New York City
- Orthopedics**
 - Shriners Hospital for Crippled Children Chicago
 - St Mary's Group of Hospitals St Louis
 - Robert Packer Hospital Sayre Pa
 - Children's Orthopedic Hospital Seattle
- Otolaryngology**
 - Flower Fifth Avenue Hospital New York City
 - Temple University Hospital Philadelphia
 - Gill Memorial Eye Ear and Throat Hospital Roanoke Va
- Ophthalmology**
 - Collis P and Howard Huntington Memorial Hospital Pasadena Calif
 - Children's Hospital Washington D C
 - Binghamton City Hospital Binghamton N Y
 - Temple University Hospital Philadelphia
 - Elizabeth Steel Magee Hospital Pittsburgh

- Urology**
 - St Mary's Group of Hospitals St Louis

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL December 11 page 2011

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination Feb 14 16 May 9 11 (limited to a few centers) June 20 22 and Sept 12 14 Ex Sec Mr Everett S Elwood 225 S 15th St Philadelphia

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Written examination for Group B applicants will be held in various cities throughout the country April 16 Applications due Feb 15 Oral examinations for Group A and B applicants will be held at San Francisco June 13 14 Sec Dr C Guy Lane 416 Marlboro St Boston

AMERICAN BOARD OF INTERNAL MEDICINE Examinations will be held in various centers of the United States and Canada Feb 14 Final date for filing applications is Jan 1 Chairman Dr Walter L Biering 406 Sixth Ave Suite 1210 Des Moines Iowa

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written examinations and review of case histories for Group B candidates will be held in various cities of the United States and Canada Feb 5 General oral clinical and pathological examinations for all candidates (Groups A and B) will be conducted in San Francisco June 13 14 Application for admission to Group A examinations must be on file before April 1 Sec Dr Paul Titus 1015 Highland Bldg Pittsburgh (6)

AMERICAN BOARD OF OPHTHALMOLOGY San Francisco June 13 All applications and case reports in duplicate must be filed at least sixty days before the date of examination Sec Dr John Green 3720 Washington Blvd St Louis Mo

AMERICAN BOARD OF ORTHOPAEDIC SURGERY Los Angeles Jan 14 15 Sec Dr Fremont A Chandler 6 N Michigan Ave Chicago

AMERICAN BOARD OF OTOLARYNGOLOGY San Francisco June 10 11 Sec Dr W P Wherry 1500 Medical Arts Bldg Omaha

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York Dec 29 30 Sec Dr Walter Freeman 1028 Connecticut Ave NW Washington D C

AMERICAN BOARD OF RADIOLOGY San Francisco June 10 12 Sec Dr Earl R Kirkin 102 110 Second Ave SW Rochester Minn

Vermont June Examination

Dr W Scott Nay, secretary, Vermont State Board of Medical Registration, reports the written examination held at Burlington June 16-18 1937. The examination covered 12 subjects and included 90 questions. An average of 75 per cent was required to pass. Twenty-six candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Tufts College Medical School	(1936) 84 1	86 1	82 2
University of Vermont College of Medicine	(1937) 78 9	80 7	84 4
	86 1	86 1	87 2
	88 1	88 8	88 8
	88 1	88 8	89 3
	89 3	89 4	89 6
	89 6	89 6	89 9
	90 7	97 3	

Ten physicians were licensed by endorsement from January 27 through October 12. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad of
College of Medical Evangelists	(1935) A B M Ex	
Georgetown University School of Medicine	(1934) Mass Penna	
Boston University School of Medicine	(1916) Mass	(1934) A B M Ex
Hahnemann Med College and Hospital of Philadelphia	(1934) New Jersey	
Univ of Vermont College of Medicine	(1935) (1936 3) A B M Ex	

* License withheld pending completion of internship

Colorado October Report

Dr Harvey W Snyder, secretary, Colorado State Board of Medical Examiners reports the written examination held at Denver Oct 6 8 1937. The examination covered 8 subjects and included 165 questions. An average of 75 per cent was required to pass. Two candidates were examined both of whom passed. Six physicians were licensed by endorsement on October 5. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine	(1937)	84	
University of Oklahoma School of Medicine	(1937)	84	

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad of

Creighton University School of Medicine	(1936)	Nebraska
University of Nebraska College of Medicine	(1936)	Nebraska
Jefferson Medical College of Philadelphia	(1929)	U S Army
University of Wisconsin Medical School	(1929)	Utah

Book Notices

Textbook of Diagnostic Roentgenology By Lewis J. Friedman, M.D., Director Roentgen Ray Department Bellevue Hospital, New York. Cloth. Price \$10. Pp. 623 with 638 illustrations. New York & London: D. Appleton Century Company, Incorporated, 1937.

The increasing utilization of the roentgen rays for diagnosis has brought about a need for more treatises on the subject. This book tends to fill the hiatus which exists between the small textbook for students and the large, detailed volume for the roentgenologist. There are three distinct classes of readers whose needs must be met: the undergraduate student, the general practitioner and the specialist in roentgen diagnosis. In a book of this size covering a subject whose scope is so broad, it is extremely difficult to satisfy all these groups. In this volume the student is given insufficiently exact descriptions of x-ray signs and differential diagnostic features. There is a glaring deficiency in the omission of any discussion of the indications for roentgen examination and of the relative value of the method. For the specialist in this field the treatment is too brief to be of great value. For the practicing physician who wishes quickly to find information on some feature of roentgen diagnosis, this book will prove to be most helpful. The author presents a short but clear summary of the fundamental physics of radiation. This, together with the inclusion of sections on x-ray technique, even including dark room procedures, will no doubt also appeal to the general practitioner. Normal appearances are well described and there is a commendable attempt to present the common anatomic variations, particularly of the bones. Nevertheless, certain normal variants, such as the epiphysis of the tuberosity of the fifth metatarsal, the inferior accessory lobe of the lung and the prepyloric notch of the stomach, are omitted. The illustrations are generous and well reproduced. The line drawings are instructive and clarifying. There is an unfortunate tendency both in the text and in the illustrations to present the more unusual manifestations of disease, which may give the unwary reader a wrong impression. For the roentgenologist the illustrations are perfectly clear, but for the student or general practitioner more elaborate labeling and larger captions would be desirable. There are a number of specific criticisms, of which a few examples may be cited. The impression is created that the usual examination in cases of intestinal obstruction is by means of the barium meal, probably a harmful procedure. The use of the term "chronic myocarditis" is vague and misleading. The discussion of bone tumors, a most important subject, is much too brief. The observation of a peripheral triangle in lobar pneumonia can hardly be said to be a rare observation. On the whole, however, the errors are not reprehensible. A bibliography is appended to each chapter. It would be well to point out that this was not intended, in any sense to be complete. Otherwise a reader, unfamiliar with the roentgen literature, might be misled by the extreme paucity of references with regard to certain subjects. This volume covers a great deal of ground and for so short a book is unusually complete. It should be a valuable addition to the library of the general practitioner.

Analyse physique des calculs urinaux et biliaires Par le Dr. E. Pillet. Paper. Price 25 francs. Pp. 96 with 68 illustrations. Paris: Masson & Co., 1937.

Dr. Pillet's small volume contains the results of his study of urinary and biliary calculi by physical means. He has subjected stones after comminution into minute particles to mineralogical examination especially by means of the polarizing microscope. Crystallography, he states, is a science by which exact determinations can be made. These determinations should be made more widely known as the use of a new method of examination brings with it new facts which may have an important value in the analysis of the subject of calculi formed in the human body. By the use of polarized light each type of crystal found in urinary calculi has certain distinguishing physical characteristics which are constant. For example oxalate stones are made up of small octahedrons and appear on section as lance shaped or as spherulites depending on whether the urine is clear or contains blood. Calculi of uric acid have a lamellated structure quite different from the isolated crystal. Calculi of

ammonium-magnesium phosphate are agglomerations of large flat crystals. Crystals are pyro electric, which means that elevations of a fraction of a degree of temperature are sufficient to produce electrical potential at the extremities of the crystal. This type of investigation is interesting but highly technical and its value to the understanding of the pathogenesis of stone will necessitate more research and the critical application of the data furnished.

Charterhouse Rheumatism Clinic Original Papers Volume I. Cloth. Price \$5.25. Pp. 203 with illustrations. New York & London: Oxford University Press, 1937.

This book requires careful study. In order to appreciate it one must have a keen interest in the subject and approach the material contained in the book with a very open mind. It is technical, the apparatus is expensive and the deductions have not been proved. The application of the pathogen selective cultures and sedimentation rate is made to various groups of arthritis and assists in a clearer understanding of the etiology, differential diagnosis, prognosis and therapeutics. The book contains an interesting clinical, radiologic and serologic correlation on spondylitis adolescents. Roentgenography makes the diagnosis on the basis of sacroiliac joint abnormalities long before the symptoms become manifest clinically. This early aid in diagnosis of disabling spinal affliction affords an advance in prophylaxis and therapy. There will be fewer undiagnosed or misdiagnosed early cases. Early treatment by roentgen irradiation, in dosage determined by sedimentation rate tests and clinical progress evaluation by sedimentation rate tests at regular intervals is recommended. The rheumatic patients are divided into ten classes, each of which is discussed individually. The book is divided into three parts: The Pathogen Selective Culture and Its Bearing on the Classification and Etiology of Chronic Rheumatic Disease, by H. Warren Crowe; The Differential Sedimentation Test, by Harry Coke; and Spondylitis Adolescents with Associated Pathological Changes in the Sacroiliac Joints, by S. Gilbert Scott. This is a book for specialists rather than for the general practitioner.

Infantile Paralysis and Cerebral Diplegia: Methods Used for the Restoration of Function By Eltznabeth Kenny. With a foreword by Herbert J. Wilkinson, Professor of Anatomy and Dean of the Faculty of Medicine, University of Queensland. Cloth. Price 21s. 1p. 125 with 45 illustrations. Sydney, Australia: Angus & Robertson Limited, 1937.

This book contains discussions on infantile paralysis and spastic paralysis of infants. The author stresses the importance of restoration of function. In discussing infantile paralysis, she outlines the principles of treatment, apparatus used, treatment of complications, residual paralysis and muscle reeducation. Under the subject of spastic paralysis she discusses the condition as it is found in infants, the apparatus used in treatment, and the principles of treatment and exercises. There is a great deal of valuable information in the book and it is recommended to all those who are concerned with the diagnosis or treatment of persons afflicted with either disease or lesion. The treatment of infantile paralysis is based on the following five principles: (1) maintenance of a bright mental outlook, (2) maintenance of impulse, (3) hydrotherapy and remedial exercises, (4) maintenance of circulation, and (5) avoidance of the generally accepted methods of immobilization. There is an interesting foreword by H. J. Wilkinson, professor of anatomy and dean of the University of Queensland Faculty of Medicine.

Les péricystites Par le Dr. P. Dominici. Paper. Pp. 331 with 31 illustrations. Paris: Joue & Cie, Editeurs, 1937.

Dr. Dominici states in his preface that he has utilized the data included in the two extensive reviews on the subject of pericystitis which have appeared in the last twenty-five years: one by d'Aversenq in 1913 and the other by Paul Delbet in 1921, he has also added the many contributions in the literature bringing it to date, and has included certain material which may have escaped the notice of the two authors cited. The volume is well printed and presents the subject in an orderly and comprehensive manner. It is remarkable for the excellence and clarity of the illustrations, many of which are original. Dominici's work is an important contribution to the literature on pericystitis chiefly on account of its completeness. The bibliography and extensive case reports culled from the litera-

ture permit ready reference to the various categories in which the author has divided his subject. Reference to many American authors is made, especially the work of Clute, Young, Beer and Culver. The book has its chief value as a reference work and affords an encyclopedic exposition of the subject.

The Technic of Local Anesthesia. By Arthur E. Hertzler. M.D. Ph.D. Professor of Surgery in the University of Kansas. Kansas City, Kansas. Sixth edition. Cloth. Price \$5. Pp. 284. St. Louis: C.V. Mosby Company, 1937.

This edition considers the few good anesthetics that are available for local anesthesia, the doses and the methods of their use, the combination of epinephrine with local anesthetics and the combination of local anesthetics and general anesthesia. There is a description of the syringes and needles recommended for this work and various other appliances that are conveniently used for this type of work. The various blocks are described on an anatomic basis, as for example in chapter IV, local anesthesia for operations on the scalp, the cranium and its contents, and in chapter V, local anesthesia for operations on the face, jaw and tongue. In the following chapters local anesthesia is described for operations on the ear and mastoid cells, for trifacial neuralgia and for operations on the fifth cranial nerve, cervical lymph nodes, buccal soft parts, thyroid gland, tonsils, larynx, trachea, mammary gland, thorax, lungs, spinal column and abdomen. Paravertebral and splanchnic anesthesia are dealt with in a chapter as well as sacral and transsacral block anesthesia. There is a special chapter on spinal anesthesia written by Dr. Irene A. Koeneke, and this method is considered in considerable detail. There are further chapters on local anesthesia for operations on inguinal and femoral hernias and also for umbilical, linea alba and scapular hernias, and for operations on the penis, scrotum, urethra, bladder, prostate gland, female organs and rectum, and upper and lower extremities. There is a short chapter on intravenous anesthesia with sodium amytal, which has not been used much clinically as a surgical anesthetic since 1930. The subject of preliminary medication is discussed briefly. This is a useful book for the general surgeon because the author's preference is infiltration of tissue to be incised, which is the most effective method for use by the general surgeon unless he also has been trained in regional methods of anesthesia. There are 142 excellent illustrations.

The Pneumonokonioses (Silicosis). Literature and Laws. Book III. International Abstracts, Extracts and Reviews of the Pneumonokonioses and Their Associated Diseases and Subjects. By George C. Davis. M.D. Associate Clinical Professor of Surgery, Rush Medical College, University of Chicago. Ella M. Salmonsens, Medical Reference Librarian, the John Crerar Library, Chicago, and Joseph L. Earlywine, Attorney at Law, Chicago. Cloth. Price \$8.50. Pp. 1033. Chicago: Chicago Medical Press (Not Inc.), 1937.

Book III is similar in all respects to books I and II which appeared respectively in 1934 and 1935. The present book embraces 701 abstracted articles related to dusty lung diseases all of which appeared in 1935 and 1936. In addition, a small section is devoted to earlier publications overlooked in previous compilations. Such material, together with several indexes make up part I of the present book and represents 900 pages. Part II of this volume presents the occupational disease laws of the United States and some mention of foreign countries. Taken in their entirety, these three books provide the best compilation in the English language of published materials related to dusty lung diseases. Book III is larger than either predecessor, which in part is due to the inclusion of large numbers of nonscientific discussions of dusty lung diseases such as have appeared in lay papers. A few of these items represent abstracts of commercial promotional items in lay publications. The elimination of approximately one third of the abstracts would have made this valuable compilation even more valuable. It is observed that in the text of the entire series the term 'silicosis' appears in parenthesis by the side of the pneumonokonioses. Manifestly, silicosis is not a synonym of the pneumonokonioses, although silicosis is one of the pneumonokonioses. The previous publications in this series have been given favorable reception by physicians, attorneys, engineers and industrial hygienists. There is no reason to believe that this book will prove any less useful or any less popular, even though it appears at a time when dramatic concern in silicosis, so prevalent a few years ago, is now distinctly on the wane.

Soubor prací venovaných Profesoru V. Libenskému na počest jeho šedesátých narozenin. Recueil de travaux dédiés au Prof. V. Libenský en l'honneur de son soixantième anniversaire. Československá lékařská společnost. Number 22, June 7, 1937. Cloth. Pp. 277 with illustrations. Prague: Société Tchécoslovaque de Cardiologie, 1937.

This collection of articles in honor of Prof. Václav Libenský's sixtieth anniversary is presented in book form, divided into two parts. The first part contains sixty-two pages of articles contributed in French and Italian by various foreign authors, the second and larger part presents articles contributed in Czechoslovakian by native authors, each having a French or English summary. The articles are mostly on subjects of internal medicine, the circulatory system being given the preference. The articles are rather short, but all are interesting and written by well known authors.

The Kinesiology of Corrective Exercise. By Gertrude Hawley. M.A. Assistant Director, Women's Gymnasium, Stanford University, California. Cloth. Price \$2.75. Pp. 268 with 107 illustrations. Philadelphia: Lea & Febiger, 1937.

Active exercise, because of its wide applicability and its importance in developing the body to the highest possible mechanical efficiency, probably should be given first place in the many agents used in physical therapy. This small volume, which is intended for students, teachers and physical therapists specializing in the field of corrective exercise, is a practical textbook on kinesiology. The exercise treatment of infantile paralysis, spastic paralysis and fractures is not discussed, but it does give exercises suitable for use in any corrective or remedial physical education department where a reasonable amount of personal supervision can be given by the instructor. It can be recommended to teachers interested in this branch of physical education.

Quantitative Pharmaceutical Chemistry Containing Theory and Practice of Quantitative Analysis Applied to Pharmacy. By Glenn L. Jenkins. Ph.D. Professor of Pharmaceutical Chemistry, College of Pharmacy, University of Minnesota, and Andrew C. DuMez. Ph.D. Professor of Pharmacy and Dean of the School of Pharmacy, University of Maryland. Second edition. Cloth. Price \$3.50. Pp. 466 with 67 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1937.

This book covers both general and physical methods used in official pharmaceutical analysis as directed by the United States Pharmacopeia and the National Formulary and aims to develop a logical explanation for the various steps in the analysis as well as presenting questions and problems which are intended to develop the student's reasoning capacity. The first chapter is an excellent introduction to general chemical analytical methods, including simple statistical presentation of results and presentations of such calculations as probable error, gravimetric methods applied to official substances, volumetric analysis, alkalimetry, acidimetry, precipitation methods, oxidation and reduction methods and gasometric methods. Part II is devoted to an exposition of physicochemical methods used in official assaying. In part III, special methods such as ash and moisture determinations, extractive and crude fiber content and analyses of drugs for proximate principles are taken up. This book bears the stamp of many years of experience in teaching and should be a welcome laboratory manual, most especially for students in colleges of pharmacy.

Aids to Physiology. By Henry Dryden. Ph.D. M.R.C.S. L.R.C.P. Professor of Physiology, Royal (Dick) Veterinary College, Edinburgh. Second edition. Cloth. Price \$1.25. Pp. 295 with 63 illustrations. Baltimore: William Wood & Company, 1937.

A book for the rapid reviewing of facts in a science is occasionally an aid to a candidate for an examination but is ordinarily useless for study. This book is reasonably accurate and is well composed. It is essentially a dictionary arranged under the conventional headings of the physiologic and anatomic subdivisions of the body. All aspects of the subject are covered, but in brief and dogmatic form. One defect in such a work is that the reader has no way of knowing which of the statements are well substantiated and which are not. In physiology today many qualifications must be made and questions left unanswered because of inadequate knowledge. It would be highly undesirable to recommend this work as a student's textbook.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Failure to Observe Symptoms of Eclampsia—The plaintiff, as administrator of the estate of his deceased wife, sued the Columbia Clinic, Inc., and Dr Hackett, an employee of the clinic, attributing the death of his wife to their negligence. The jury returned a verdict against the clinic but for Dr Hackett, and the clinic appealed to the Supreme Court of Washington.

The Columbia Clinic, Inc., was a corporation operating a hospital in the city of Longview with the usual staff of physicians, nurses and attendants. The plaintiff, an employee of a company operating in the vicinity, had a "family contract" for the medical care and hospital treatment of the members of his family by the Columbia Clinic, Inc. April 21, 1934, he and his wife went to the hospital, saw Dr Hackett and advised him that the plaintiff's wife was pregnant and expected to be confined in about a month. Dr Hackett apparently made the usual examination and inquired into the facts of the case and the family history of the expectant mother. He gave directions as to how the patient should conduct herself and asked her to bring in for examination, at intervals, specimens of her urine. According to the physician's testimony, the condition of the patient at that time was normal. Samples of urine were brought in on two later occasions which Dr Hackett testified indicated a normal condition. The patient was taken to the hospital about 5 o'clock on the morning of May 28 and placed in the care of a nurse then in charge, and Dr Hackett was notified of her arrival. He did not go to the hospital until about 8 30 and did not then see the patient. He did, on his arrival at the hospital, look at the hospital chart, which, he testified, showed that the case was progressing with normal labor. Later, Dr Hackett found that his services as a surgeon were required in a case involving severe injuries and asked another member of the hospital staff, a Dr Clark, who specialized in obstetric cases, to take care of the patient. Dr Clark did not see the patient until 11 45 a. m. He then made what the record refers to as a cursory examination and concluded that the patient was normal and that the case was proceeding normally. At 1 40 p. m. Dr Clark again saw the patient made a further examination and again concluded that everything was progressing normally. At that time he expected delivery within two hours. About 2 o'clock the patient suffered a convulsion and Dr Clark was immediately called and found her in a comatose condition. She was rushed to the delivery room and the baby was delivered within fifteen minutes by the use of forceps. The patient was then taken to the maternity ward and put to bed. The nurse there in charge was informed of what had taken place and was told to watch the patient and to advise Dr Clark of developments.

Dr Clark saw the patient later in the afternoon and, as he testified, "talked to her, asked her how she was, turned around and came out again." Dr Hackett looked in to see the patient in midafternoon and both Dr Hackett and Dr Clark visited her at about 6 p. m. At neither time, according to their testimony, did either see anything wrong and no treatment was ordered except that which is given in a normal case. Beginning about 7 o'clock in the evening the patient again had convulsions and from that point on it seems to be conceded that she received proper treatment, notwithstanding which in a few hours she died. It was the plaintiff's theory that certain symptoms were present when Dr Hackett first examined the patient which indicated at that time the presence, or the prospective presence of eclampsia. Lay witnesses testified that such symptoms were then present but Dr Hackett testified to the contrary. Medical testimony was introduced to the effect that eclampsia being present or there being present the symptoms from which it may be expected that it will develop, there is a known treatment which should be at once applied and which, when applied will greatly lessen the probability of a fatal ending. No such treatment was given to the patient until after she again had convulsions at 7 o'clock in the evening, after the birth of her child.

Dr Hackett did not treat the patient after she came to the hospital but turned the case over to Dr Clark. There was therefore, the court said, a wide open opportunity for the jury to find that Dr Hackett was not negligent but that the nurse who received the patient at the hospital was negligent in not discovering the symptoms of eclampsia and recording them on the hospital chart so that Dr Hackett, when he read the chart might have ordered the proper and necessary treatment. The symptoms of eclampsia are such, the court said, as should be observed by a nurse even though she might not know what was indicated thereby. Furthermore, the jury might have found that Dr Clark was negligent in one or more of several ways (1) by his failure to see the patient until 11 45 a. m., more than six hours after her arrival at the hospital and at least two or three hours after the case had been turned over to him by Dr Hackett, (2) by not then discovering the symptoms of eclampsia and ordering the proper treatment and (3) by his failure to discover the symptoms at the time of the delivery of the baby or subsequently during the afternoon and then ordering a treatment which would probably have prevented the development of eclampsia and the return of the convulsions. There was evidence, also, from which the jury could have found that the nurse in the maternity ward was negligent in not keeping a closer watch over the patient during the hours following delivery and in not observing and calling attention to the symptoms then present. It seems clear, the court said, from these facts that the jury could, as it did exonerate Dr Hackett and yet, by finding negligence on the part of some other employee of the clinic, render a verdict against it. The charge and the proof was such as to permit the jury to find any one or more of four employees to be guilty and a verdict in favor of the employee who was made a party is not a finding that another or other employees, not parties, were not guilty.

The judgment of the trial court, therefore against the clinic was affirmed—*Hansch v Hackett et al (Hansch)*, 66 P (2d) 1129.

Workmen's Compensation Acts Diabetic Gangrene Precipitated by Trauma—The petitioner, a night watchman at the building of the defendant trust company, was afflicted with diabetes, though apparently he did not know it at the time of the accident. While he was making one of his rounds he stubbed a toe on which there was a callous area against a chair. He at once felt acute pain in the toe, which increased during the course of the night. The following morning he was taken to a hospital dispensary and reported to the physician there that he had stubbed his toe against a chair. Two days later when he returned to the hospital diabetes was suspected and an examination of the urine confirmed that suspicion. Signs of incipient gangrene were then observed. From this point the case progressed to an amputation of the leg below the knee. The petitioner instituted proceedings under the workmen's compensation act of New Jersey and obtained an award. This award was affirmed by the court of common pleas, Passaic County and the trust company brought certiorari to the supreme court of New Jersey.

In the opinion of the supreme court, the evidence tended to show that an accident in the course of employment and arising out of it was a substantial contributing cause of the disability sustained by the petitioner. The inference was entirely reasonable from the testimony that the accident incited a tendency to gangrene existing because of the diabetic condition of the petitioner. The award was therefore affirmed—*Cahill Franklin Trust Co (N J)* 191 A 748.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Blood Sugar in Diabetes in Children—Kantrow and Boyd investigated the nocturnal fluctuations of the blood sugar level of diabetic children the blood sugar level in the early morning hours after awakening but before the ingestion of food or the administration of insulin, and the response to standardized doses of insulin unaccompanied by food. In all 299 separate tests were completed, 207 with diabetic and ninety-two with nondiabetic subjects. Since the blood sugar level of the diabetic subject reacts at a different tempo from that of the nondiabetic subject, an insulin tolerance test may prove as valuable a means of diagnosing the presence of diabetes as is the dextrose tolerance test. The hyperglycemia of hyperthyroidism may be distinguished from that of diabetes in this manner. The test as performed consists of the administration of one fourth unit of insulin per kilogram of body weight and the determination of the blood sugar level before and at four half hour intervals subsequently. The maximal reduction in the nondiabetic subject is observed within the first half hour whereas in the diabetic subject the fall is prolonged into the second or third half hour or longer. This peculiarity of response seems inherent in the diabetic organism and is not determined by the initial blood sugar level nor is there evidence that the nature of the response is altered by treatment of the disease.

New Tuberculin Patch Test—Vollmer and Goldberger describe a new patch test, which has the advantage of simplicity over other tuberculin tests. Thin filter paper is saturated with tuberculin suspended in the air in a room free from dust and allowed to dry. This saturated filter paper when dry can be kept indefinitely. The paper is cut into 0.8 cm squares and placed on adhesive tape with forceps. Three types of plasters are prepared in this way: (1) plasters equipped with old tuberculin, (2) plasters containing old tuberculin and bouillon control and (3) plasters containing old tuberculin control material and bovine tuberculin. The distance between these squares must be at least 1 cm. When more than one square is used each square is distinguished by a specific letter on the back of the plaster. The adhesive side of the plaster can be protected with stiff gauze. By the natural moisture of the skin this tuberculin is liquefied sufficiently to cause a cutaneous reaction. In spite of this dilution by moisture the tuberculin remains sufficiently concentrated to cause a reliable cutaneous reaction. The control square does not cause an inflammatory reaction. However, a sensitive skin may occasionally give a

nonspecific irritative reaction caused by the adhesive plaster. Therefore it is always best to use a control square. In carrying out the test the skin is cleansed with ether or benzene and the plaster, from which the gauze has been removed, is placed securely on the skin. After twenty-four hours the reaction was read. The results were more reliable when the plaster was left on for forty-eight hours. The reaction may be read immediately after removal or twenty-four hours later, at which time possible nonspecific skin reactions have disappeared and the tuberculin reaction is intensified. When positive, the reaction appears as a sharply defined, indurated, reddened square, with lichenoid, follicular elevations on the skin. Reactions are usually cleared when the plaster is put lengthwise on the sternum or transversely over the upper edge of the trapezius muscle. This eliminates spreading of the tuberculin as the result of folds in the skin. The reliability of the test can be seen in that 187 of 209 tuberculous children or 89.5 per cent showed a conformity between the results of the Pirquet test and those of the present patch test. The results that did not correspond were in fifteen children who showed a negative reaction to the Pirquet test and a positive reaction to the patch test and in seven children who showed a positive reaction to the Pirquet test and a negative reaction to the patch test. The fundamental principle of the tuberculin patch test with saturated filter paper proved, after modification, to be fit also for an allergy patch test.

Relation of Anemia of Chronic Glomerulonephritis to Gastric Acidity—Since previous studies on the anemia of nephritis have failed to utilize more accurate methods Townsend and his associates felt that the application of the hematologic technique to their patients would enable them to classify their anemias more definitely, might give some clue toward the recognition of the fundamental defect present in the anemia of nephritis and possibly suggest a more efficacious treatment, and that an assessment of the gastric acidity might disclose some correlation between the developing anemia, nitrogen retention and diminishing gastric acidity. The refractory nature of the anemia to iron therapy has always been a puzzling one and suggests that such medication may fail because of a disturbed gastric secretion. Their observations on the character of the red blood cell in the anemia of chronic glomerulonephritis permit them to classify the anemia as one of the normocytic variety, but in some of the individual cases the

hemoglobin content is slightly lower than that commonly associated with this type of anemia. A deficient supply of erythrocytic building material might be considered the possible explanation for this type of picture. It is common knowledge that the anemia of chronic glomerulonephritis does not respond to iron, and the slightly lower hemoglobin found in the individual red cell is probably of significance and compatible with the thought that the anemia is due to a deficiency of blood cell forming material. Studies on the gastric acidity tend to support this view. The most important features in the anemia of chronic glomerulonephritis is the diminished or absent hydrochloric acid in the gastric secretion, and this diminution must play an important part in the improper digestive processes and improper absorption of food and iron. The investigations indicate that there is a correlation between the decreased renal function, the development of a normocytic anemia and the development of a low to absent secretion of free hydrochloric acid. The low gastric acidity, by interfering with the proper metabolism of ingested food and the absorption of iron, indirectly produces a deficiency of "building material" for sufficient red blood cell formation and the production of hemoglobin.

Deficiency Syndromes Associated with Chronic Alcoholism—Physical, neurologic and psychiatric examinations were carried out in 131 cases of chronic alcoholism. Romano paid particular attention to the dietary history, presence or absence of polyneuritis, anemia and clinical response to vitamin B therapy. The age period between 30 and 50 contained more than 64 per cent of the 131 patients, sixteen were women. Eleven of the women and sixty-four of the men had some qualitative inadequacy in their diets for varying periods previous to admission. Of the seventy-seven patients who showed evidence of some form of neuritis, sixty-one gave a history of inadequate diets. Ten of the female patients and sixty-seven of the male patients suffered from some degree of peripheral neural involvement. Eleven of the women and sixty-four of the men suffered from some degree of anemia, although fifty-six of the total number of patients with some degree of anemia had only mild involvement. Of the nineteen patients who had moderate or severe anemia, six had macrocytosis as revealed by increased cell diameter and volume index. Iron and ammonium citrate in large daily doses (from 4 to 8 Gm) together with parenteral liver were successful in treating the anemias. Every patient with mild moderate or severe peripheral neural involvement was placed on a high caloric high vitamin diet (from 4000 to 5000 calories daily) the quantity of protein obtained from lean meat being increased and the carbohydrate decreased. This diet was supplemented with dried brewers' yeast tablets (4 Gm daily) wheat germ preparations (from 30 to 60 Gm daily) and either vitamin B₁ or preparations of liver given parenterally in daily doses. In addition to this, fresh orange or tomato juice together with various preparations of cod or halibut liver oil were given. Of the seventy-seven patients with neuritis, five failed to respond to vitamin therapy, forty-seven showed partial improvement and twenty-five showed complete improvement with specific therapy during their period of hospitalization (average 24.67 days).

Electroencephalogram in Schizophrenia During Insulin Hypoglycemia—Hoagland and his associates made electroencephalographic records during thirty-five insulin treatments of six schizophrenic patients. Electrical brain waves after large doses of insulin show a progressive decline in the frequency of the alpha wave (Berger rhythm) of some 40 per cent, which parallels with a time lag of some minutes (about thirty) the declining blood sugar curve. Sugar injected during coma restores the frequency along a smooth curve. The present data along with other evidence, are in accordance with the view that alpha frequencies are directly proportional to the rate of carbohydrate metabolism of the cortical cells producing the rhythm.

Roentgen Demonstration of Bleeding Duodenal Ulcers—Hampton describes a method for the demonstration of dangerously bleeding duodenal ulcers. It permits profile, direct and double contrast examination of the posterior wall of the stomach, the pyloric valve and the posterior wall of the duodenum. The entire examination is done with the patient in a horizontal position when compression or palpation is contraindicated or impossible. The equipment necessary for the examination consists of a horizontal roentgenoscope and a quick change over switch, which will allow the taking of films rapidly during roentgenoscopic observations. The patient should be shifted from the hospital truck to the roentgenoscope table on a stretcher. The barium suspension must be prepared carefully. An electrical mixer is recommended. There are certain already prepared barium mixtures on the market which can be used.

The author uses by volume 4 ounces of plain barium sulfate, 3 ounces of water and 1 teaspoonful of liquid petrolatum with agar. More barium can be added by the addition of liquid petrolatum with agar without increasing the viscosity of the mixture. The mixture should be freshly made and of about the consistency heavy cream. After the patient has ingested the barium meal as he lies on his back, he is rotated toward his right side and allowed to remain in this position under roentgenoscopic observation until the first part of the duodenum has filled and emptied two or three times. Then when the duodenum is completely filled he is promptly returned to the face-up position and rotated more to the left side until the pyloric valve and first portion of the duodenum are seen in profile. Roentgenograms are taken with the roentgenoscopic tube immediately while the duodenum is still filled and when abnormalities are noted, but it is when the patient is lying face up slightly rotated to the left, that the best examination of the duodenum is obtained. The inner relief of the posterior wall of the duodenum can be visualized by taking films after the duodenum has emptied. Thick barium will adhere to the duodenal mucosa and by the force of gravity will remain in such ulcerous craters as are present. The double contrast examination is then done. There is usually a gas bubble present in the stomach, but if there isn't the patient should be instructed to swallow four or five times. When the fundus gas bubble is in the antrum, pyloric valve and duodenum films are taken for double contrast examination. This allows a study of the gastric and duodenal relief exactly as is obtained by the double contrast enema.

Treatment of X-Ray Sickness with Vitamin B₁ Hydrochloride—Martin and Moursund observed that in animals deprived of vitamin B₁ symptoms similar to those seen in x-ray intoxication develop. The four major points of similarity are loss of appetite, changes in intestinal motility and tonus, changes in the mucous membranes of the gastro-intestinal tract and alteration of the sugar metabolism. For more than six months, patients with x-ray sickness have been treated with oral or intramuscular injection of vitamin B₁ hydrochloride and the clinical results were most striking. A series of animal (gunea pig) experiments has been carried out in an effort to establish a sound basis for the use of this preparation. The experimental results support the use of vitamin B₁ in the treatment of x-ray sickness.

New Method in Use of Radon Gold Seeds—To overcome the limited mobility of the treated part during the use of needles containing radon or radium, the inability of disposing of saliva and consequent pulmonary complications when platinum

needles are used in and around the oral cavity and the possible inaccurate placement of platinum needles, Hames outlines a radon suture method which consists in the placing of radon seeds within the lumen of a specially made silk carrier. The spacing between openings into which the radon is placed can be varied at will. Those that he used in his cases were all placed 1 cm apart. The usual filtration of 0.3 mm of gold has been employed, but this may be increased as desired. After the radon seeds are placed in the body of the woven silk material, they are permanently sealed in place by the closure of the woven structure and also by a plastic substance containing carmine as an indicator of the area in the suture in which the radon is situated. The spaces between the implants are filled with silk, so that there is a uniform diameter of the suture material throughout its length. On one end of the suture is a small, permanently attached metal collar. The distal end of this collar is threaded to receive the needle of whatever type may be desired. The needle is threaded at one end in order to permit its being screwed into the metal collar. The needle is passed through the tissue around or beneath the area to be treated and the proper placement of the suture is guided by the red markings indicating the point of radon activity. After the suture is so placed, a glass bead is threaded over either end and brought to rest against the tissue. Above this bead a lead shot is fixed to hold the material in place until such time as its removal is desired. In removing the device the suture is cut below the fixed bead and withdrawn in a manner similar to that used in removing an ordinary cutaneous suture or capillary drain. When it is unnecessary or impossible to use a needle, the radon loaded suture may be packed into the cavity—as the antrum or the uterus—after being attached to the usual packing gauze, and its removal readily accomplished by removing the packing. The method provides a means of using radon by the average surgeon, who may be distant from the source of supply of radium and radon.

Ingrown Toenail—Heifetz summarizes the present status of the subject of ingrown toenail and presents a routine of treatment which he has used for several years. The main underlying causes of ingrown toenail are ill fitting footwear and improper cutting of the nails. The use of cotton packing, if properly applied, is one of the simplest effective means of conservative treatment. Radical operation is simplified in the method of Winograd, which the author uses with modifications in certain cases. From three to five days before operation depending on the infection present, the patient soaks and cleanses his foot in warm water (110 F) for an hour twice a day. The operative field is made bloodless by the application of a tourniquet. From 3 to 4 cc of a 2 per cent solution of procaine hydrochloride is injected on each side of the toe at different sites. An incision three eighths inch long is made in the eponychium and proximal wall of the nail, extending slightly diagonally laterally from a point on the nail corresponding to the line on which the nail will presently be excised. This is made deep enough to strike the root of the nail. Medial and lateral flaps are dissected along this line so as to expose at least the lateral third of the root of the nail on that side. The lateral flap should also include sufficient tissue so as to expose the embedded edge of the nail. A small thin flat spatula similar to the Bollenger-Hajek nasal elevator is inserted beneath the free border to the nail between the plate and the bed of the nail along the line where the nail is to be cut, and, hugging the undersurface of the nail, is pushed proximally until it emerges in the incision proximal to the root of the nail. This spatula is then worked laterally until it lifts the involved portion of the nail from its bed. The freed involved portion of the nail is excised along a straight line, exposing the bed of the nail, and, proximally, the matrix on that side. By means of a sharp small bone curet the exposed matrix is completely curetted away. The wound is thoroughly swabbed with a cotton applicator soaked in 95 per cent phenol, and then with alcohol. This is done to destroy any fragment of matrix that may have become implanted in the wound. If considerable infection is present a small wick of iodoform gauze may be inserted under the flaps. No special closure of the wound is necessary. The flaps will fall back into place themselves and any dead space will be eliminated by the application of a tight dressing. The wound is first covered by a layer or two of

petrolatum gauze, snugly encircling the terminal phalanx. A few small pieces of plain gauze are then similarly applied, and several turns of a roller bandage made. The tourniquet is cut, starting considerable fresh bleeding, but this is promptly controlled by completing the bandage. On the day following operation, the patient wears a cut-out shoe and is permitted to walk and resume as much of his normal occupation as he desires. On the second day after operation he returns for his first dressing, at which time the blood encrusted dressings are removed, if a drain has been inserted, it too is removed, a smaller petrolatum gauze dressing is then applied. On the sixth or seventh postoperative day, when healing has well progressed, two or three 2 by 0.5 cm strips of adhesive tape are applied directly to the wound in such a way as to pull the lateral flap in the direction of the cut edge of the nail. A small dry dressing is applied over this. Thereafter, dressings of adhesive tape are applied every three or four days until complete healing has occurred. Beginning about the eighth day, the patient makes a daily attempt to wear his regular shoe. Twenty-nine operations were performed on twenty patients in accordance with the described technique. All were followed for at least six months, some as long as eighteen months. There was a complete and satisfactory cure in all.

Rectal Evipal as Complete Anesthesia—Hogan reports observations on 200 patients given rectal evipal as a complete anesthesia. The depth of anesthesia is easily controlled by means of metrazol. Postoperative pulmonary complications have been markedly reduced in his hospital since the introduction of the technique. Postoperative distress has decreased and hospitalization of the patient has been reduced by from one to three days. In some cases the relaxation in the abdomen has not been satisfactory and it is his belief that the addition of a small amount of ether in oil to the rectal evipal will eliminate this factor. Clinical observations along these lines are proceeding.

Cure of Gonococcal Infections in Women—In order to find a basis for the criteria of cure in gonorrhea Wharton followed up his seventy-six private patients that he treated in the last ten years. There were twenty-one cases in children, thirty-three cases in adult women treated without operation and twenty-two cases also in adult women receiving radical treatment. In gonorrheal vaginitis of children, his criterion of cure is complete absence of gonococci in smears for approximately six consecutive months, the smears being taken at least once a month. Gonococcal vaginitis in children can be completely and permanently cured and it can be determined whether a child has been rendered noninfectious. The first criterion is a long observation of these patients through the various stages and final localization of the disease and the knowledge that the infected foci have been either excised surgically or destroyed completely by the actual cautery. The other criteria are repeated follow up examinations with negative observations for one year, repeated negative smears and continuously negative history of infection both personal and marital. The com-

plement fixation test may eventually deserve to be included among the criteria of cure. There is no single, simple cast test which will infallibly indicate the presence or absence of gonorrhea. Approximately 90 per cent of the author's patients are well. Some have married and borne healthy children without any infection in either the husband or wife. Therefore gonorrhea in women can be cured and there are reliable criteria of cure.

Use of Ducrey Vaccine in Diagnosis—Dulaney presents the results of 260 skin tests on 125 individuals, from which it is seen that an easily demonstrated allergy is present in persons infected with *Haemophilus ducreyi* and that a positive cutaneous reaction is indicative of present or past infection. In fifty patients showing lesions that were clinically chancroid positive reactions were obtained in forty-six. Two of the negative results were given by patients in the early stages of the disease who had not developed buboes, and it is accepted that such involvement increases cutaneous reactivity. Two patients with typical lesions of the surface and buboes failed to react to either the Ducrey or the Frei antigen. Cutaneous sensitivity is demonstrable early in the disease, as early as ten days (patient's history) after the appearance of the ulcer but in most cases allergy manifests itself at a later date. The reaction increases in intensity with time. Cutaneous sensitivity, once developed is very lasting and must always be remembered in practical use of the test. While both chancroidal pus and bacillary antigens may be used for cutaneous testing purposes, the latter elicits much more definite reactions. It also affords a method of standardizing such a diagnostic procedure. The high incidence of coexisting venereal lymphogranuloma and chancroidal infection necessitates a careful selection of material for antigens and especially for Frei tests.

Phenylpyruvic Oligophrenia—Jervis studied fifty cases of phenylpyruvic oligophrenia. Twenty-one patients were inmates at Letchworth Village, thirteen patients were examined at the Wassau State School, eight at the Rome State School and eight, who were sibs or institutionalized patients, were examined at their respective homes. Examination of the members of the family of thirty-five patients showed that phenylpyruvic acid did not in any instance occur in the urine of mentally normal members. The clinical manifestations in their constitutional, neurologic and psychological aspects, appear to occur with a certain constancy and are sufficiently characteristic to afford justification for regarding them as constituting a fairly well defined clinical syndrome. Critical examination of the anamnestic data seems to exclude any relation of exogenous agencies to the etiology of the disease, whereas the family incidence of the disease suggests that a genetic mechanism is of etiologic significance. Statistical elaboration and critical analysis of the genetic figures are

justification for regarding the condition as determined by a single recessive gene substitution. Clinically, the disease is characterized by pronounced intellectual defect coexisting with neurologic symptoms. These consist of extrapyramidal manifestations (rigid posture, muscular hypertonus and hyperkinesias) and exaggeration of the deep reflexes. Characteristic constitutional features are found in the majority of cases. From a biochemical point of view the condition appears to be an error of the metabolism of phenylalanine, consisting essentially of a failure to oxidize further a normal catabolite, phenylpyruvic acid, which consequently is excreted as such in the urine.

Postural Defects Related to Arthritis—Hartung declares that defects in bodily posture affect patients with arthritis in five ways. 1. Poor posture is a mechanically inefficient carriage and therefore requires an undue amount of energy in standing and sitting. In this way it adds one more burden to the already overburdened constitutional inadequacy of these patients. 2. It produces ptosis of the gastro intestinal tract and decreases the vital capacity of the lungs. This embarrasses the normal function of these organs. 3. It predisposes to pains in the lower part of the back. 4. It causes undue trauma at certain joints, predisposing these to the localization of arthritis. In osteoarthritis, in which the process is generalized this static trauma localizes the development of pain in certain crucial areas such as in the lumbosacral and cervical spine, the knees and the feet. 5. It has a depressing psychologic effect. Chronic arthritis is a constitutional disease and until a clear idea is had of its etiology the most effective treatment must be directed toward the various constitutional derangements presented by these patients. Muscular exercise in itself unless properly planned will not correct postural defects. The key-stone of defective posture is often a lumbar lordosis and the associated pelvic tilt. To correct lumbar lordosis, emphasis is placed not on exercises alone but on developing a conscious control especially of the gluteal and abdominal muscles. Without gaining this neuromuscular control no amount of exercise will bring about satisfactory improvement in posture.

Protamine Zinc Insulin and Carbohydrate Tolerance—Greenhouse attributes the increased carbohydrate tolerance of diabetic patients given protamine zinc insulin to the continuity of its effect and its prolonged action. It furnishes a basic insulin supply by creating a depot from which insulin is regularly and continuously liberated so that the body has available a supply of insulin at all times over a period of at least twenty-four hours. The metabolism of the diabetic patient is

thus more adequately stabilized, offering particular respite to the pancreas and liver. Protamine zinc insulin finds its greatest usefulness in the case in which the diabetes is in part at least functional, rather than in cases of diabetes in which the pancreas is so sclerosed as to allow for no improvement. Improvement occurred most frequently in the large middle aged group of patients.

Chronic Pylonephritis and Arterial Hypertension—During the last ten years fifteen children between 3 and 11 years of age were observed by Butler at necropsy to have pylonephritis. Records of the blood pressures of seven of these patients are not available. The records of the blood pressures for the remaining eight patients show systolic pressures ranging from 250 to 140 mm of mercury and diastolic pressures from 170 to 110 mm of mercury, the average systolic and diastolic pressures being respectively 190 and 140 mm of mercury. Two of these patients had hypertensive crises and died of cardiac failure before significant nitrogen retention occurred. The clinical histories of two others of the group studied pathologically indicated that the pylonephritis and hypertension preceded severe nitrogen retention. During the same ten years three patients with pylonephritis and hypertension died but permission for necropsy was not obtained. The histories of two of these patients indicate that the pylonephritis and hypertension preceded significant renal insufficiency and nitrogen retention. During this period nine patients with pylonephritis and hypertension were admitted to the hospital and when last seen were living. Of these patients only one had renal insufficiency, and in this one the pylonephritis

and hypertension preceded the appearance of the diminished renal function. Thus there have been fifteen patients (six dead and nine living) who have had chronic pyelonephritis and hypertension over a period of years before there was appreciable diminution in the function of the kidney. There is no definite proof that the pyelonephritis preceded the hypertension. A patient, coincident with a ureteral calculus, was found to have a unilateral pyelonephritis and during the course of the next eight months hypertension and cardiac failure developed. The removal of the one infected kidney was followed by clearing of the urine and a return of the blood pressure to normal, where it has remained for twenty months. There is strong evidence that the pyelonephritis preceded the hypertension and in some way had a causal relation to it. The study has led to the hypothesis that the hypertension might well be related to the local effect of the pyelonephritis rather than to the renal insufficiency encountered late in the disease.

Oxidation of Dextrose in Normal and Diabetic Men—Sheldon and his collaborators compared the oxidation of dextrose in normal and diabetic men. When the three normal male subjects were studied in the fasting state, the amount of carbohydrate oxidized in the four hour period became larger as the carbohydrate of the preparatory diet was increased. This effect was consistently obtained when the carbohydrate in the preparatory diet was varied between 25 and 500 Gm. Further, when the dextrose was ingested at the beginning of the experimental period in amounts from 50 to 200 Gm, even though the carbohydrate preparation had been the same, the oxidation of dextrose was increased. When both the carbohydrate of the preparatory and chamber periods were simultaneously increased, the oxidation of dextrose was additive. The three diabetic subjects studied were free of any disease other than the diabetes mellitus. The amount of dextrose oxidized in the four hours was dependent on the severity of the patient's disease. However, the response to increasing the dextrose of the chamber period is similar to the response of the normal subjects, but quantitatively reduced. When the same subjects were studied after a period of from twenty-three to thirty-five days of constant hyperglycemia and glycosuria, the amount of dextrose oxidized in four hours stayed at a constant level even though the dextrose of the chamber period was increased from 0 to 100 Gm. Emphasis is placed on the inability to increase oxidation of dextrose in response to the ingestion of increased amounts of dextrose, a marked contrast to the normal controls who oxidized more dextrose when they ingested more of it. Increasing the carbohydrate preparation from two to three times above the tolerance of the diabetic patients resulted in but a slight increase in the amount of dextrose oxidized. This slight increase may be attributed to the associated hyperglycemia which produced a maximal stimulation of the mechanism for the utilization of carbohydrate. Once the maximal stimulation has been reached, further ingestion of dextrose can never result in additional oxidation.

Action of Sulfanilamide in Empyema—Gay and Clark state that sulfanilamide prevents the evolution of an invariably fatal streptococcal empyema in rabbits when it is given repeatedly and in sufficient doses subcutaneously. Complete steriliza-

tion of the inoculated cavity occurs on approximately the second day. The serum, defibrinated blood and artificial pleural exudate of similarly treated animals inhibits the growth of the same streptococcus in the test tube, but even repeated doses of such treated blood serum fail to sterilize the culture. The coccic chains grown in such drugged serum are elongated and present pleomorphic and metachromatic organisms and may give rise to colonies that are at first less predominantly mucoid in appearance. Such organisms have lost little if any of their virulence. Cooperation on the part of locally derived clasmatocytes is apparently required in complete sterilization of the animal body. Sulfanilamide apparently produces a bacteriostasis sufficiently marked to protect the accumulated leukocytes and to allow the natural defense macrophages to accumulate. There is direct evidence that the drug does not in itself stimulate the mobilization of the macrophages. There is no evidence that the cell reaction which finally accounts for disposal of the organisms is other than local.

Untreated Seronegative Mothers of Syphilitic Children—Waugh states that only two untreated seronegative mothers of children with prenatal syphilis were admitted to the United States Public Health Service Venereal Disease Clinic, Hot Springs, Ark., during the seven years 1930 to 1936. Blood serum Wassermann reactions, spinal fluid examinations and careful physical examinations revealed no evidence of syphilis in these two mothers. There is no doubt that their two children had prenatal syphilis rather than acquired syphilis, as both children had bilateral interstitial keratitis, Hutchinsonian upper central incisors, saddle noses and 4 plus blood serum Wassermann reactions.

Fever Therapy in Children—Spektor and McBryde believe that severe reactions of fever therapy can be avoided by careful observation of the patient before and during treatment. The benefits derived from fever therapy outweigh the risks, especially in gonorrheal infections. Treatment at high temperature is not devoid of danger. At Duke Hospital about 430 fever treatments (at temperatures varying from 104 to 106.7 F) have been given to 280 patients (thirty-two children 248 adults). Four deaths occurred in adults. If the patient tolerates the first three hours of fever, the remaining two to nine hours of treatment usually will progress smoothly, provided there is an adequate intake of fluid the patient is fairly quiet and the temperature is not allowed to go above 106.7 F. In the thirty

two children, artificial fever has been used in treating gonorrheal infections, chronic infectious arthritis, syphilis, chorea encephalitis, Hodgkin's disease, tuberculous meningitis, undulant fever, interstitial keratitis and leukemia

The Patient with Acute Alcoholism—Friedewald states that during the last two years there were 1,887 cases of alcoholism admitted to the St Louis City Hospital. About two thirds of the cases were classified as acute. Fifty of the patients died and necropsies were obtained on nine of them. In these cases alcohol was considered either the immediate or the contributory cause of death. In the necropsies all but two cases showed marked fatty infiltration of the liver. The brain was examined in only three of the cases, two showed cerebral edema and the other showed rather marked cerebral atrophy. Four cases showed a bronchopneumonia. One patient, a man aged 45, a chronic alcohol addict who entered the hospital vomiting blood and in shock, at necropsy showed an acute gastritis with erosion of blood vessels and resultant hemorrhage. While the patient with acute alcoholism can usually be given a good prognosis for recovery, a number of these cases are real medical emergencies and require accurate diagnosis and active treatment. The treatment depends on the condition of the patient and the stage of the alcoholism. Ordinarily evacuation of the stomach by means of a stomach tube followed by a saline purgative is indicated. Apomorphine may be used, which also acts as a hypnotic. In the excitement stage, sedatives are necessary. Paraldehyde, bromides and chloral hydrate are the drugs used most commonly. In the depressant stage caffeine or strychnine is used as a stimulant. Acute alcoholic coma causes a dangerous respiratory depression, paralysis and cyanosis. Death may be prevented and recovery accelerated by the inhalation of 90 per cent oxygen and 10 per cent carbon dioxide for a time sufficient to reestablish normal color and respiration. Since the alcoholic patient is usually in a state of starvation and avitaminosis, he must be given a high calorie diet rich in all vitamins supplemented with large doses of vitamin B. Patients showing cerebral edema with symptoms of increased intracranial pressure are given chloral hydrate and sodium bromide rectally for sedation. Saline purgatives and hypertonic dextrose intravenously aid in relieving the cerebral edema. Repeated spinal drainage also is recommended. A complication that can be overlooked easily is that of hypoglycemia. Most chronic alcohol addicts have fatty livers and there is little glycogen present. Fractures of the skull, lacerations, bruises and the like must always be kept in mind when examining an acute alcoholic patient. Fracture of the skull can be easily overlooked in an unconscious alcoholic patient.

Narcolepsy and Its Treatment with Benzedrine Sulfate—Ulrich reexamined his cases of narcolepsy that have been treated with benzedrine sulfate for nearly two years. No permanent deleterious effects were noted, and there was no evidence of habit formation. Some of the patients complained of temporary disturbances, including anorexia especially if the drug was taken before meals. Slight temporary elevation of the blood pressure and of the basal metabolic rate was produced in a few cases but no permanent effect of that nature was observed. Although the need for caution in the presence of vascular hypertension is emphasized, a case is reported in order to show that hypertension, arteriosclerosis and senility are not absolute contraindications to the use of benzedrine in suitable cases. Loss of weight was the result of the treatment in several obese patients. This is believed to have been due in part to the lessened appetite that may result from the use of the drug and in part to the change from periodic quiescence to a state of greater mental and physical activity. Harm may come from the careless and uncontrolled use of benzedrine in the treatment of narcolepsy especially in otherwise healthy young persons. Dibenzyl carbinamine, a related compound, was tried in a few cases. It had no beneficial action on the narcoleptic state, and its deleterious effect on the gastro-intestinal tract was greater than that of benzedrine. Oral medication with benzedrine sulfate appears to be the only satisfactory method of treatment.

Infections of the Middle Ear—Crebbin states that a study of middle ear infections is facilitated by knowledge of the anatomy of the temporal bone, which at birth and for months thereafter, consists of three distinct parts: the squamous, the tympanic and the petromastoid. At this period in life these principal parts are held together by a connective tissue which ossifies slowly and as a rule, the connection between them is imperfect at the end of the first year. Usually there is no sharp demarcation between an infection of the middle ear and infection of the mastoid. The borderline between an attack of acute catarrhal otitis and an attack of acute suppurative otitis is indefinite. The deciding factor

depends on the type and virulence of the invading organism, the resistance of the patient and the anatomic peculiarities. Earache is the most common symptom in acute infections of the middle ear. There is usually tenderness over the mastoid antrum and tip. Deafness may be present. There is loss of appetite and sleep. Temperature is variable and is not a dependable sign. Convulsions and meningitis may be present from the onset. The appearance of the tympanic membrane is characteristic, but this changes with the progress of infection. There is a lack of luster to the membrane and loss of light reflex. There is usually more or less bulging and redness. At times the appearance of the membrane may be gray instead of red. A patient showing these symptoms should have a myringotomy as soon as possible. An early myringotomy performed amid strict surgical surroundings is generally accepted as a safe procedure. A myringotomy will not cure all patients, for further treatment is ordinarily necessary, and even a mastoidectomy may finally be indicated. A liquid diet, with an abundance of fruit juices, and sunshine are indicated. Carotene in oil and cod liver oil preparations are of great help. A hematologic study and repeated roentgenograms should be made in each case. A swab of the pus is taken after a myringotomy or from the cavity after a mastoidectomy and a vaccine prepared and used if there is delay in the cessation of the aural discharge or delay in the healing of the wound. Vaccines are more effective if autogenous, freshly prepared and started in small doses. The author urges that the dry method of treating be followed in all cases of acute suppurative otitis media. An adenectomy and tonsillectomy should be done as soon as the acute symptoms have passed. A thorough conservative treatment is always indicated in an acute suppurative otitis media. If there is no improvement after a reasonable time, a mastoidectomy is indicated. A preliminary transfusion is indicated especially if the patient is a very sick child or in a weakened condition. Following a mastoidectomy, transfusions will shorten the duration of the disease and hasten the recovery of the patient. Any patient with chronic suppuration of the middle ear is potentially in danger of his life. Infants and young children should be given a general anesthetic, whereas young adults and adults should have a local anesthetic. The author has had most satisfactory results in using the Miller zinc ionization machine in cases that do not respond to the usual accepted treatment in chronic suppurative otitis. Three cases are cited which show the value of this treatment.

Knee-Chest Exercises in Postpartum Retrodisplacement—Eichner studied 316 women having 402 deliveries in the obstetric service at Mount Sinai Hospital, 227 per cent of the uteri of 211 patients instructed in knee-chest exercises during their stay at the hospital were found in a posterior position at their first dispensary examination, while 277 per cent of the uteri of the 191 patients not so instructed were retroplaced at their first postpartum examination. In the entire series 101 patients or 25.1 per cent of the total, had retrodisplacements at their initial postpartum visit. The percentage of posterior displacements increased with the parity from 20 in the primiparas to 41.2 in the quintigravidas, 30.4 per cent of the posterior displacements treated by knee-chest exercises were failures and of these six patients responded to the use of a pessary and seven were discharged. In cases in which the pessary failed the knee-chest position also failed. In twelve patients the uterus became anterior without treatment for the

retrodisplacement in an interval less than that required for either pessaries or knee-chest exercises. The conclusion is that knee-chest exercises are valueless in the treatment of postpartum retrodisplacement except during the third and fourth weeks of the puerperium, when these exercises appear to reduce the percentage of displacements.

Pancreatitis—Friedenwald declares that the incidence of acute and chronic pancreatitis is far greater than is recognized and, as the symptomatology of these conditions is usually indefinite, the correct diagnosis is too rarely made. Acute hemorrhagic pancreatitis is ushered in by a sudden violent pain in the epigastrium, with signs of shock, which may suggest rupture of a peptic ulcer, of the gallbladder or even of the appendix. It may be followed by death within a few hours or days. The acute gangrenous form follows the hemorrhagic type in which the symptoms have been of a milder or subacute form. This condition manifests itself by the appearance of chills fever and the formation of a mass in the epigastrium within a week or two after the onset of the hemorrhagic stage. The acute suppurative type frequently ensues as a subsequent stage after either of the first two types. It is associated with chills fever and frequently jaundice, nausea, vomiting and severe epigastric pain. Fat necrosis is an important diagnostic accompaniment especially of hemorrhagic and gangrenous pancreatitis. When the disease has progressed to the gangrenous and suppurative stages speedy operation is indicated. Although the symptoms of chronic pancreatitis are rarely definite its presence should be suspected if in a patient who has suffered from chronic dyspepsia there is present a severe or slight epigastric pain associated with nausea, vomiting, emaciation, extreme weakness, slight jaundice and occasionally pyrexia and intermittent glycosuria. In many instances the bulky, soft fecal and o stools containing undigested fat and protein aid in arriving at

the diagnosis. The duodenal contents for pancreatic ferments may be markedly diminished in their activity in this condition. In the prophylactic treatment, attention must be especially directed to the early removal of gallstones before complications have occurred and, as preventive measures, a carefully regulated diet should be followed, together with nonsurgical biliary drainages. When the disease is definitely established, immediate operation is advised. If gallstones or pancreatic stones are present, they should be removed and infection overcome.

Initiation of Respiration in Asphyxia Neonatorum—Wilson and his associates aver that the treatment of asphyxia neonatorum has not kept pace with other advances in obstetrics. A thorough understanding of drugs, anesthetics and resuscitation should be part of the knowledge of every obstetrician. Less than 5 per cent of the volume of oxygen in the blood of the umbilical vein is accompanied by clinical evidence of asphyxia. A brief fall below 1 per cent of its volume is not necessarily fatal, but longer exposures cause permanent damage to the delicate nerve cells of the center and resuscitation is no longer possible. New evidence is presented indicating that the atelectatic lung cannot be opened by gases under pressure in the trachea. Pressures as high as 18 mm of mercury fail to open alveoli and result in damage to the lung tissue. Lower, and therefore safer, pressures are even less efficacious. Respiratory depressant drugs and anesthetics are discussed and listed in the order of their safety. Morphine alone or in combination has other purposes during labor besides the relief of pain. Because of this it should be administered expertly not less than two hours before delivery. No one method of resuscitation is entirely satisfactory. A method for obtaining graphs of the apnea and early respirations of the new-born is described. The method furnishes conclusive evidence of respiratory status at birth and the effects on the baby of drugs and anesthetics administered to the mother before delivery and shows the efficacy of various methods of resuscitation. In severe cases of asphyxia and respiratory depression the injection of a respiratory stimulant is logical and to a large extent the only possible way of producing a respiratory gasp. An improved technic for the administration of respiratory and cardiac stimulants, saline solutions and so on by means of the umbilical vein is described.

Cystic Changes in Endometrium—By microscopic examination of twenty eight specimens of endometrium Randall and Herrell observed that cystic changes occurred in all phases of the menstrual cycle. In those endometriums in which cystic changes occur in the proliferative phase there is often an accompanying proliferation, so called hyperplasia, of a greater degree than occurs normally. Thus a polypoid endometrium is usually

increased in thickness, although the microscopic picture of the proliferation remains the same. As the differential phase appears and increases, this proliferation is less and less noticeable, but the cystic changes persist. Atypical bleeding was not present in any case in which a well differentiated endometrium was associated with cystic changes. Those tissues in which cystic changes were found in the early differential phase were not infrequently associated with atypical uterine bleeding. In cases in which a cystic endometrium was in the late proliferative phase of the menstrual cycle, atypical bleeding was more frequently present. The essential difference in these specimens of the endometrium is the degree of differentiation which must exist because of a difference in the activity of the hormone of the corpus luteum. There is microscopic evidence that the function of the corpus luteum is not on an all or none basis. Cystic changes are common in the endometriums of women at the beginning of the menopause, when the first phase of ovarian failure is commencing. Ovarian failure is essentially the same among younger women and should be accompanied by the same microscopic appearance of the endometrium.

Relation of Carbon Dioxide to Artificial Respiration—Johnson points out that a modification (raising and lowering the arms at the elbows alternately with prone pressure) of the Schafer prone pressure method has been proposed by Hederer. An evaluation of this method has indicated the possibility of increasing the pulmonary ventilation in the Schafer method by more than 40 per cent. The great sensitivity of the respiratory center to carbon dioxide is well attested by the fact that artificial respiration applied to the extent of lowering the alveolar carbon dioxide as little as 0.2 per cent below normal is sufficient to cause apnea. On the other hand, when the alveolar carbon dioxide pressure is raised by only 2 mm the breathing is increased about threefold. If the carbon dioxide of inspired air is increased to 4.5 per cent it is impossible to produce an apneic pause, however forcefully the artificial respiration may be carried out. There seems no reason to avoid the conclusion that every form of manually applied artificial respiration should be accompanied by the inhalation of carbon dioxide whenever possible. The use of an apparatus of the type of the H-H inhalator is recommended in connection with artificial respiration.

*Demonstration of Tubercle Bacillus in Pulmonary Tuberculosis of Childhood. S. Campbell—p. 321

Demonstration of Tubercle Bacillus—Campbell describes the advantages of the various methods of demonstrating the tubercle bacillus and attempts to establish the comparative value of the aids to diagnosis in a series of fifty suspected children. In the efforts to demonstrate the tubercle bacillus in pulmonary tuberculosis, the greatest success was obtained by culture of the washings of the stomach. Of the twelve cases in which the tubercle bacillus was eventually isolated culture on Loewenstein-Jensen medium was carried out in ten instances and was positive in eight, i. e., 80 per cent. Of the twelve positive washings from the stomach, sputum was obtained in eight instances and of these five, or 63 per cent, disclosed the presence of the bacillus. In addition to the lower proportion of positive results from examination of the sputum the difficulty, indeed the impossibility, of always obtaining the sputum must be taken into consideration. Although the children resent lavage of the stomach, the swallowed sputum can always be obtained. Direct smear of the washings of the stomach was much less frequently positive than was culture. In the ten positive cases in which culture was carried out the organism was found by direct smear in five. Animal inoculation was also less frequently positive, as in only five of the ten cases was the organism isolated. The risk of the animals dying from intermittent disease and the long time required for the test are further drawbacks.

Dural Sinus Thrombosis in Early Life—Bailey and Hass made a study of three children who presented organized and canalized thrombi in the superior longitudinal sinus. These three instances were found at necropsy in a series of eighty cases of sinus thrombosis of all types. One patient developed acute neurologic disturbances in the course of cardiac decompensation resulting from mitral stenosis of rheumatic origin. At necropsy, organized and canalized thrombi were found in the superior longitudinal and right lateral sinuses. There was a zone of organizing hemorrhage and softening in the cerebral cortex. The other two patients were infants who developed normally up to the time of their acute illnesses, characterized by severe diarrhea and vomiting. During the illness of one patient and shortly after the subsidence of acute symptoms in the other patient it became obvious that there was impairment of mental function. Death occurred several months later. Portions of the superior longitudinal sinus of each patient contained organized and canalized thrombi. The pathologic changes in the brain and meninges allowing for such repair as might be expected after a few months, conformed with those changes which are commonly associated with thrombosis of the superior longitudinal sinus of short duration. The authors believe that the study gives support to their contention that certain acquired cerebral defects are due to thrombosis of the superior longitudinal sinus and its sequels. The organ-

ized thrombi may be small and easily overlooked, as unless the entire lumen is occluded the process of organization tends to reduce their size greatly. A thorough search of the dural venous sinuses for the presence of organized thrombi may elucidate the causation of some instances of focal cerebral gliosis, "encephalitis" of childhood and spontaneous subdural or subarachnoid hemorrhage.

Cerebral Infection with *Schistosoma Japonicum*—Greenfield and Pritchard present clinical and pathologic data which refer to two patients, each of whom presented a symptom complex suggesting the presence of a cerebral tumor and in whom operation disclosed a mass in the brain identified as a collection of eggs of *Schistosoma japonicum*. If a patient who is known to have sojourned in a part of the world infested with *Schistosoma japonicum* later has focal epileptic attacks the possibility should be considered that these may be due to a collection of the eggs of this parasite in the brain. Changes that give support to such a conclusion are undernourishment with a mild secondary anemia and a high eosinophil count in the blood and with a high protein and cellular content in the cerebrospinal fluid. Confirmatory evidence should be looked for in the stools. Eggs of the parasite were found in the stools of both patients. The prognosis is good when operative removal of the tumor is followed by a course of antimony tartrate.

Retinitis of Pregnancy—Duggan and Chitnis present three cases of retinitis of pregnancy, the first case represents the characteristic form of retinitis, the second case belongs to the group of toxemia of pregnancy complicated by chronic nephritis and the third one exhibits features resembling the first one, yet its nature remains obscure. There is only one type of retinitis which can be called retinitis of pregnancy, that described by Semple characterized by sudden onset, edema of retinal tissues, equally sudden cessation on removal of the cause and complete restoration of vision. Whenever chronic nephritis complicates pregnancy, the visual disturbances are due to renal retinitis. This retinitis is associated with high blood pressure, which, together with the signs of retinitis has a tendency to persist after delivery. This form of retinitis is a useful guide in differentiating chronic nephritis complicating pregnancy from preclampsic toxemia. It should really belong to the group of cases in which hypertension and chronic nephritis are present before pregnancy. Apart from their differentiating value lesions of the retina help in estimating the damage done to the vascular tree. In the presence of commencing retinitis, the ophthalmologist should not hesitate to advise interruption of pregnancy.

Rapid Method for Isolation of Organic Poisons—Stewart and his co-workers find that in the extraction of alkaloidal poisons from the viscera the laborious and time-consuming Stas Otto process may be replaced by treatment of the minced

material with trichloroacetic acid. This at once yields a water-clear filtrate free from protein and fat, and containing the whole of the alkaloid originally present. From this filtrate the alkaloid can be removed by adsorption on kaolin, from which after neutralization it is eluted by hot chloroform. After removal of the alkaloids, barbital can be adsorbed on charcoal and eluted with ether. The method is being tested further and extended to other organic poisons.

*Clinical Aspects of Tuberculous Cervical Lymphadenitis B C Thompson—p 466

Clinical Aspects of Tuberculous Lymphadenitis—Thompson maintains that tuberculosis of the peripheral lymph nodes has decreased considerably during the past quarter of a century, possibly more than any other form of tuberculosis. Nevertheless, it still remains a relatively common disease and in Great Britain is by far the commonest cause of chronic massive enlargement of the lymph nodes. Any large persistent swelling of the lymph nodes of the neck without an obvious local focus is to be regarded as tuberculous until proved otherwise. In 324 cases of peripheral tuberculous lymphadenitis the author has found the supraclavicular and axillary lymph nodes affected only one third as often as the upper cervical group. This form also showed a tendency to appear later in life, with a maximal incidence at the age of 15, compared with nine years in the latter type. More than half of this group showed x-ray evidence of intrathoracic tuberculosis, which usually took the so-called childhood form, with one or more small foci in the periphery of the lung and massive enlargement of the tracheobronchial lymph nodes. Calcification was usually present in these lesions. Much less commonly the associated pulmonary disease was of the adult type, with extensive cavitation and fibrosis and no mediastinal adenopathy. By reason of its pulmonary origin and the associated tracheobronchial disease, tuberculosis of supraclavicular and axillary lymph nodes has a significance quite different from that in the nodes of the upper part of the neck. It should, of course, be remembered that tuberculosis tends to spread from one group of lymph nodes to the next, by either normal or retrograde paths. Those unusual cases in which tuberculosis involves simultaneously the upper cervical and tracheobronchial lymph nodes, between which there is no direct anatomic connection, are probably due to concomitant infection of both the upper and the lower parts of the respiratory tract.

Lead Poisoning from Cooking Utensils—Sen reports a case in which a person bought new metal cooking pots in March 1936 and, having had them lined (with tin and lead) used them from April. In May attacks of colic, abdominal distention and diarrhea began and these became worse in June. He recovered from the attack, possibly because the lead from the lining had been removed and he had by then excreted the poison from his system. The symptoms recurred with greater severity about the end of September after more utensils were lined. He then had been using the newly lined cooking pots

for a couple of weeks. This time the attack was acute and his admission to the hospital apparently saved him from a much worse attack. From the fact that when the patient left the hospital there was little left of the lining of the pots it could be surmised that a large portion must have become dissolved in the articles cooked within a couple of weeks of beginning to use these pots—hence the acuteness and the severity of the symptoms. The fact that the patient was living largely on milk probably prevented him from suffering complications, as he was unwittingly administering to himself the antidote with the poison. With regard to lead poisoning, no systematic study has been made of its incidence and prevention as an occupational disease. It is suggested that an organized inquiry might be held into the question of lead poisoning of the workmen engaged in lining these pots and also of the persons who use them for cooking. It is possible that legislation might be found advisable to prevent such poisoning.

Weil's Disease in India—The workers who have successfully cultivated *Leptospira* from the blood of patients with Weil's disease are inclined to the view that successful results are obtained only when the blood cultures are taken within the first seven days of illness. Das Gupta and Chopra obtained a positive blood culture as late as the ninth day (from what they believe to be the first case in India), but the guinea pigs inoculated at the same time proved refractory to infection. Although found in fairly large numbers in the urine, the leptospirae were always immobile and most of them showed varying degrees of degeneration. This is probably due to the presence of plenty of bile (which has a lytic action on *Leptospira*) still present in the urine.

Gold Salts in Treatment of Arthritis—Hartfall and his colleagues have employed chrysotherapy in the treatment of 900 cases of arthritis, 750 of which were of rheumatoid arthritis. They maintain that preparations of gold constitute the best single form of treatment in rheumatoid arthritis. They are still unable to predict toxic reactions, although they are at present investigating a patch test which appears to be giving promising results. The factors on which toxic reactions depend are still unknown, but from their experience they feel justified in drawing the following tentative conclusions. Certain individuals undoubtedly show an idiosyncrasy to gold salts, developing multiple reactions after small doses, and these patients are presumably unsuitable for treatment. In others there are no doubt several factors, dosage is of some importance. The maximal single dose should not be more than 0.1 Gm and a course of injections should not consist of more than 1 Gm. At the same time larger doses produce even more striking results. It is probable that some preparations of gold are more toxic than others, but their toxicity does not appear to be dependent on the route of injection. Age and sex severity and duration of the disease appear to have no bearing on the frequency of reactions nor has any relationship been found between the blood sedimentation rate and the development of toxic reactions. There are a few real contraindications to treatment with gold salts: any history of previous purpura or agranulocytosis appears to be an absolute contraindication as is gross renal or hepatic disease. Rheumatoid arthritis, if seen in its early stages can be cured by gold salts, and there are few cases that cannot be improved to some extent. Any acute nontraumatic monarticular arthritis should be regarded as the possible forerunner of widespread and severe rheumatoid arthritis. Every patient should have at least two courses of injections and a persistently raised blood sedimentation rate is an indication for further treatment with gold salts.

Agglutination Test in Weil's Disease—Smith and Tulloch point out that in view of the experience of one of them (Tulloch) when investigating the agglutination reactions of separated bacterial flagella it seemed probable that, although cultures of *Leptospira* do not show much turbidity before exposure to antibodies, they could, on such exposure under suitable conditions, produce floccules that would be seen easily. It is possible to prepare a suspension of bacterial flagella which is virtually transparent although it contains enormous numbers of these structures. When such transparent flagellar suspensions are exposed to their appropriate (antiflagellar) serum, floccules are formed which can be seen by the naked eye, if indirect illumination is employed. In view of what is known concerning the mechanism of agglutination, it seemed highly probable that once the leptospirae were sensitized by their appropriate antibody they would not exhibit the same tendency to fragmentation on exposure to heat as they do in the unsensitized state. Should this be so, incubation at a temperature between 30 and 37 C—sensitizing incubation—could be followed by a short exposure to 55 C—flocculating incubation—in order that the rapidity of the reaction might be increased. Actually this proved to be the case. Comparative tests were made with the Schuffner procedure and the macroscopic agglutination method and the results for the two were remarkably alike. The lytic action of the Schuffner technique is not complete and apparently interferes in no way with the interpretation of the macroscopic test. The end titer of an immune serum is somewhat difficult to determine without considerable practice when the darkfield method is employed, but no particular dubiety occurs in connection with the interpretation of the macroscopic method. The ease with which macroscopic tests can be carried out and interpreted demands special emphasis, since this makes possible a much wider application of serologic methods to the study of leptospirosis, both in man and in rodents.

Schizophrenia and Its Treatment by Insulin and Metrazol—Ellery discusses the many methods of previous empirical treatment of schizophrenia and concludes that the whole point about the empirical organic procedures of the past is that, while it is better to apply treatment which will achieve sporadic success and a certain amelioration of symptoms than to stand by resignedly, not one of the methods is capable of giving results consistently better than those which are liable to occur spontaneously, if one accepts the dictum that such remissions occur in approximately 20 per cent of unselected schizophrenic patients. Complete details are given of insulin shock (Sakel) and metrazol convulsion (Meduna) therapy. To the unfamiliar observer hypoglycemic shock therapy may look particularly dangerous and somewhat cruel. However, in the hands of a competent physician who has familiarized himself with all aspects of the treatment, the dangers are often more apparent than real. From the patients' point of view the treatment is neither perilous nor painful. Amnesia prevents them from remembering any of their more distressing symptoms. Almost invariably patients gain weight and begin to feel more physically fit. This together with the return of lucidity, more than compensates for any initial discomfort they may have experienced. By the proper use of the insulin shock treatment one is now able to anticipate some 70 to 80 per cent full remissions in schizophrenic patients whose illness is of less than

six months' duration, and approximately 60 per cent of full remissions in those whose mental disorder has persisted for not more than eighteen months at the time of treatment. For patients who have been ill for longer than eighteen months the chance of achieving a remission diminishes rapidly as the length of the illness increases and as defect symptoms are manifest, but from the not altogether negligible number who do seem to recover, nearly 50 per cent show varying signs of improvement. With metrazol therapy in 50 per cent of unselected cases, in which the length of illness has varied from one week to ten years, a good remission has been obtained. In especially early cases, before the onset of permanent symptoms of mental deterioration, the reaction to this form of treatment has been most favorable, and Meduna states that he has brought about a remission in 80 per cent of such cases. Reviewing his results in individual cases, he finds that a good response may be anticipated in schizophrenic patients in whom symptoms have not persisted for more than four years. He has failed absolutely to produce any good results in patients whose symptoms have persisted for a longer time. The best responses to metrazol have been achieved in the catatonic and hebephrenic types of schizophrenia. Until results are published Meduna's figures must stand, a challenge to the modern psychiatrist confronted with the schizophrenic problem. Conclusions are drawn from both methods of treatment. The epileptic state is common to the two procedures, and a tentative suggestion is put forth that this may act by changing the biochemical milieu of the human organism in a beneficial way not yet understood, or that it may act merely as a shock, serving by its very intensity to bring the patient into a state of dependence, so that he can obtain benefit from the individual attention of those around him, together with common sense psychotherapy consciously or unconsciously applied by the physician.

Epinephrine in Vaginal Plastic Operations—It has been the custom of Furber for eighteen years to inject into the superficial tissues a 1:350,000 solution of epinephrine hydrochloride in physiologic solution of sodium chloride when doing vaginal plastic operations. The procedure eliminates the continuous drip method, maintains a clear field (which favors greater accuracy of dissecting and suturing) and diminishes loss of blood. The original method of the continuous drip allowed a large volume of saline solution to flow over the operative field, carrying away an unknown and often large quantity of blood from the dissected tissues. The solution spreads in a natural plane of cleavage, and dissection is greatly facilitated. For a cystocele of average size about 10 cc of solution is required, and a similar amount for an average cervical repair. It has been suggested that reactionary hemorrhage and delayed union or malunion of the tissues might follow the use of such a method. Furber and Duggan have watched carefully and have never experienced the former, and they have been unable to observe any change in the uniting powers of the tissues in several hundred cases. Their share of secondary hemorrhages has been no more than that experienced by most gynecologic surgeons.

Study on Vascular Reactions of Brain—Studies made by Villaret and his associates demonstrate the opposition that exists between intense reactions in the arterioles of the pia mater in case of solid embolism and the complete absence of vasomotor response at the time of gaseous embolism in the same vessels. Their experiences on solid cerebral embolism make it possible for them to make evident in an objective manner a phenomenon the significance of which has often been invoked and denied in neurology but the existence of which, in the form of spasm of the cerebral arteries, had never been verified. Henceforth, its authenticity cannot be doubted. However, in view of the short duration of the observations and of the absence of anatomic controls, the authors regard all physiopathologic deductions on this subject as premature. On the other hand, they stress the importance of their observations for the physiologic problem of cerebral vasomotoricity. They brought the proof of the possibility of producing spasms of the cerebral vessels by direct endovascular excitation, just as Riser had emphasized the existence of spasms by exogenic, either mechanical or electrical, irritation. The experimental gaseous embolism of the brain demonstrated, on the other hand, the complete indifference of the arteriolar walls to the embolized air bubbles. The authors were never able to demonstrate cerebral vasoconstriction in these conditions. The hypothesis of vascular spasms, often invoked recently to explain the nervous accidents of gaseous embolisms, do not seem to be well founded. The authors further state that they were able to demonstrate in the same animal, first, the complete inertia of an arteriole of the pia mater to a gaseous embolism and then the spasmodic reaction of the same vessel to solid cerebral embolism, namely, to the injection of pulverized pumice stone. However, these investigations nevertheless make apparent the possibility of an essential phenomenon in the course of gaseous embolism, namely, the circulatory arrest. Provoked by the air, which acts like a tampon and interrupts the circulation of the blood, this arrest elicits in the involved arterial region a temporary ischemia which, if prolonged, may no doubt cause grave alterations in elements as sensitive as the nerve cells. The authors think that the local mechanism of accidents resulting from gaseous embolism of the brain is a cerebral ischemia, which in turn is elicited by gaseous obstruction.

Tomography Applied to Cancer of Larynx—Canuyt and Gunsett point out that the method of roentgenologic sections (tomography), which has been found helpful in the diagnosis of pulmonary disorders, is helpful also for the examination of the larynx. It permits a comparison of the right and left side of the larynx. In applying it in pathologic disorders of the larynx and particularly in laryngeal cancer, the authors obtained encouraging results. No other method gave as precise results as did tomography and they conclude that this method represents a considerable progress in the study of the localization and extension of cancerous lesions of the larynx.

Pneumographic Study of Tumors of Lateral Ventricle—Askenasy points out that the ventriculography with injection of air, that is the pneumography of the cerebral ventricles is chiefly the work of Dandy and that this method has greatly modified the diagnosis, therapy and prognosis of the tumors of the lateral ventricle. On the basis of his own experience with this method he says that from the characteristics of the ventriculogram it seems possible to distinguish the primary intraventricular tumors from tumors that have invaded the lateral

ventricle secondarily. In the primary intraventricular tumors it is necessary to differentiate between the neoplasms situated at a distance from the interventricular foramen and those located near this foramen. The first ones determine the exclusion of that part of the ventricle which is located back of the tumor and this closed cavity is the site of a considerable dilatation. The second type of tumors, those located near the interventricular foramen, elicit a hydrocephalus that extends over the entire ventricle of the diseased side. These, however, do not generally cause a marked deformation or displacement of the lateral ventricle. In extraventricular tumors, which cause an external stenosis of the interventricular foramen (meningiomas of the small wing of the sphenoid, temporal gliomas and so on), the ventricular hydrocephalus is located on the healthy side, whereas the diseased lateral ventricle is collapsed by the cerebral edema. The secondary intraventricular neoplasms do not cause interruption of continuity in the image of the ventricle of the diseased side. The external wall of the ventricle is deformed by a mass coming from outside and the hydrocephalus, if it exists, is always much less marked than in the case of primary intraventricular tumor.

- *Renal Elimination of Bacteria Injected in Blood A Ligas—p 643
- Ambulant Treatment in Cutaneous Diseases M Agostini—p 655

Renal Elimination of Bacteria Injected in Blood—Ligas experimented on rabbits inoculated with bacterial broth cultures directly in the left ventricle or in the marginal vein of the ear. The bacteria administered were staphylococci, streptococci, pneumococci and bacilli of the coli and paracoli groups, in doses of about 1,000 bacteria for each kilogram of body weight. The urine was withdrawn by puncture of the bladder at intervals which varied from three minutes to ninety-six hours after inoculation. The sterile quality of the urine was verified before the inoculation. Cultures were made from the urine, bile, blood, kidney and spleen of the animals that died spontaneously or were killed. The different bacteria were identified. The author concludes that the kidney eliminates bacteria as though it were an inert body for the first forty-five minutes. When the bacteria are in contact with the kidney for more than forty-five minutes, anatomic lesions develop in the structure. The time of elimination varies with different bacteria. The colon bacillus and the streptococcus are eliminated in the urine three minutes and forty-five minutes, respectively, after inoculation in the blood. The passage of bacteria through the kidney induces biologic reactions of a physiologic type if bacteria are in contact with the kidney for a short time and of a pathologic type if the contact is prolonged.

M Dreyfuss—p 1311
- Experimental Osteomyelitis from Colon Bacillus L Mezzana—p 1342
- Hepatomegaly a Sequel to Undulant Fever Clinical Study G Drei—p 1368

Inflammatory Reactions of Lung in Leukemia—Dreyfuss made a microscopic study of the lung in four cases of bronchopneumonia in the course of leukemia. In one case of fibrous bronchopneumonia, complicated by the presence of many micro abscesses degenerated polymorphonuclear leukocytes predominated in the intra-alveolar exudates. There were a few lymphocytes and histiocytes. In the remaining three cases there was a leukemic reaction with proliferation of leukemic cells and histiocytes and the presence of a few polymorphonuclear granulocytes or no granulocytes at all. According to the author, the mesenchyma of the lung is frequently and intensely involved in the process of leukemia. It reacts by means of proliferations around the vessels and bronchi and at the nodules and intra-alveolar septums. The cellular picture of bronchopneumonia in leukemia depends on the functional condition of the organs concerned with the defense of the cells. When the organism can still fulfil the functions of granulopoiesis, the lung reacts to the stimulation of the inflammation by the production of exudates which are rich in polymorphonuclear leukocytes.

If the activity of the granulopoietic functions is diminished, the reticulo-endothelial system of the lung reacts by the production of leukemic cells and histiocytes, which form the interalveolar exudates in cases of this nature. If leukemic metaplasia is not advanced and if it is still reversible, the lung will show a microscopic picture of histiocytic alveolitis. If the functions of the reticulo-endothelial system of the lung are disturbed by the intensity of the leukemic metaplasia, immature leukemic cells prevail in the exudates, and sometimes they are the only cells which form the interalveolar exudates. Grave leukemic metaplasia inhibits the organic cellular defenses with consequent paralysis of the reticulo-endothelial system of the lung and absence of local cellular reaction.

*Autohemotherapy in Paralysis of Ocular Muscles R Campos—p 1439

*Experiments on Detoxicating Action of Aminoacetic Acid for Arsphenamine A Versari—p 1443

Pure Alexia Case G Palomba—p 1445

Autohemotherapy in Paralysis of Ocular Muscles—Campos reports satisfactory results from autohemotherapy in two cases of paralysis of the ocular muscles following hemiplegia of nuclear origin. The technic is as follows: Twenty cubic centimeters of blood is taken from a vein of the patient's arm and immediately reinjected at the gluteal region, which is then massaged for some time. The injections are given at intervals of two days alternately on each side of the gluteal region up to ten injections. The condition of the author's patient was slowly but progressively aggravated during the first month before he resorted to autohemotherapy. The latter induced in both cases complete regression of the symptoms and functional reestablishment in about one month. The treatment is simple and harmless.

Detoxicating Action of Aminoacetic Acid for Arsphenamine—Versari experimented on two groups of rabbits, which were given 0.25 and 0.35 Gm, respectively, for each kilogram of body weight, of arsphenamine dissolved in 5 cc of a 4 per cent solution of aminoacetic acid in distilled water. In the first group the largest number of animals survived the experiment and showed no organic alterations when they were killed, three months after the experiment. Of the animals that died, death occurred between the first and seventh days. All the control animals in the group which were given the same amount of arsphenamine without any aminoacetic acid died during the first two days of the experiment. In the second group, all the animals but one died between the fourth and fourteenth days of the experiments. The controls in the group died within seven days. The author concludes that the toxicity of arsphenamine is greatly diminished if aminoacetic acid is simultaneously administered. He believes that it synthesizes arsphenamine into a new product that is eliminated from the organism later on in the course of the reaction.

Epithelioma of Vulva Cases P Ronchi M Mazza and J J Courts—p 2073

Intolerance to Emetine with Development of Cutaneous Lesions—Lorenzo and Portnoy report a case of amebiasis. Treatment with enterovioform resulted in the disappearance of *Amoeba histolytica* cysts and paracysts from the feces. An injection of 0.03 Gm of emetine hydrochloride was given each day for five consecutive days. The second injection was followed by a cutaneous reaction of the allergic type with the appearance of local eruption and an infiltrating reaction at the point of injection. The third injection was followed by a reaction of an anaphylactic type with shock and generalization of the eruption all over the body. The fourth and fifth injections caused intensification of the eruption. The

reaction subsided on discontinuation of the emetine injections and on administration of calcium and epinephrine. After a period of rest, three series of emetine hydrochloride injections were administered. Each series consisted of two injections of 0.03 Gm of emetine hydrochloride, which were given for two consecutive days and followed by an interval of rest. The skin reaction was less severe after the second and third series of injections and did not take place after the fourth series. The authors believe that their case was one of allergy of the type of cutaneous anaphylaxis which was due to repeated organic absorption of disintegrated bacterial matter.

*Treatment of Agranulocytosis H E Bock—p 537

New Methods for Treatment of Gonorrhea C Fischer—p 553

Bee Venom as Therapeutic R Schwab—p 560

Intestinal Extracts in Allergic Diseases L Adelsberger—p 568

Treatment of Agranulocytosis—Bock points out that heretofore agranulocytic conditions have been treated with roentgen irradiation of the long bones, repeated injections of nucleotide and profuse blood transfusions. However, in acute cases of agranulocytosis these measures rarely prove sufficient for the compensation of the lack of granulocytes during the first four severe days. In an extremely severe case of agranulocytosis, transfusions with blood of a patient who had leukemia were made. This was possible because a person of the same blood group who had myeloid leukemia was available as a donor. In this connection the author points out that Schittenhelm before him had resorted to the transfusion of the blood of a patient with untreated chronic myeloid leukemia in a case of agranulocytosis. He thinks that Schittenhelm was the first who proved that severe agranulocytosis could be successfully treated with leukemic blood. The difference between Schittenhelm's case and the one described here was that Schittenhelm gave only a single transfusion of leukemic blood, whereas in the reported case fourteen transfusions were given. In the latter case of agranulocytosis, in which angina, necrosis of the gums, pneumonia and later on abscess of the thigh developed, the destruction of leukocytes was extremely severe. The quantity of leukocytes transmitted to the agranulocytic patient in the course of the fourteen transfusions was equivalent to the quantity that would have been provided by 250 transfusions of ordinary blood. The author admits that not all patients with agranulocytosis require such enormous amounts of leukocytes nor does he think that all require leukemic blood. Regarding the leukemic donor, he says that withdrawal of blood and immediate replacement by normal blood are not harmful for a patient with chronic leukemic myelosis but may even exert a beneficial influence.

Ketone Vomiting in Diabetic Children—Hungerland reviews the literature on ketone vomiting and reports a case of his own observation. A boy, aged 5, had attacks of vomiting and the examination revealed a diabetic coma. The author points out that there are contradicting theories about the genesis of ketone vomiting. He cites Schiff's remark about ketosis. Schiff maintained that ketosis may be caused by an excessive production of insulin but also by a blockage or exhaustion of the carbohydrate depots. On the basis of this theory, Schiff rejected the administration of insulin as dangerous in cases of ketone vomiting. Other authors, Fanconi among them, found insulin helpful. To be sure Fanconi admits that during the first period of acetone vomiting insulin should not be given alone but together with carbohydrates. The author thinks that Fanconi's patients had diabetes mellitus. In this

connection he discusses the symptomatology of diabetic coma, particularly the occurrence of vomiting, and points out that vomiting is more frequent in children with ketonuria than in adults. Vomiting seems to occur no matter of what origin the ketonuria may be, whether caused by hyperinsulinism or by hypoinsulinism. Deficiency of carbohydrates, excess of insulin or shortage of insulin all may lead to a disturbance in the carbohydrate metabolism which results in ketonuria. Vomiting in children with diabetic coma is only a special form of ketonemic vomiting. In the conclusion the author directs attention to the fact that ketonemic vomiting develops only in a certain type of children but that in this type of children any of the aforementioned metabolic disturbances may elicit ketonemic vomiting. As regards the treatment the author says that depending on the genesis of the disorder, carbohydrates as well as insulin, or both, may be required.

*Relation of Most Important Vitamins to Carbohydrate Metabolism H. Schroeder—p 373

Postoperative Cerebral Vascular Shock—Frisch and Hoff say that Hering demonstrated that in case of irritation at the site of the division of the common carotid artery a noticeable decrease in blood pressure takes place by way of the nerve of the carotid sinus. They themselves were interested in the question whether this process can be influenced by the pressure conditions within the cranium. They found that the carotid sinus reflex remains unchanged when the cranium and dura are opened or when hypertension is induced by kaolin. However this reflex disappears if a rather large amount of blood (30 cc.) is withdrawn from a cerebral vessel, whereas it remains unchanged in the case of withdrawal of a tenfold amount of blood from the peripheral vessels. In some instances there even develops a paradoxical reaction (slight increase in blood pressure). This reaction is caused by a central shock of the vasomotor centers. Thus it has been demonstrated that the carotid sinus reflex is dependent on a central regulating factor.

Alteration of Muscle Chronaxia by Sympathetic Influences—Weiser shows that the convulsions of tetany are not sufficiently explained by the calcium theory. He thinks that the regular concurrence of trophic and sympathetic disturbances and the dependence of tonus spasm and chronaxia on central influences suggest relations of the sympathetic disturbances and spasms to the regulatory centers in the brain stem. The demonstration of hypersensitivity does not fully explain the irritation of the muscle in tetany. Attention should be given also to chronaxia, for it is increased before the convulsion and has diagnostic significance. The chronaxia is increased in case of catheterization of the stomach, besides the hyperventilation at the onset of the examination and the possible alkalosis by the administration of acid in the further course, the mere touching of the gastric wall has an important part in the alteration of the conditions of irritation in the muscle which finally may become manifest in an actual spasm. The alteration must be explained as a reflex action. Irritation of the stump of the vagus leads in the animal experiment to a prolongation of the muscle chronaxia. This increase in the muscle chronaxia can be suppressed by the previous administration of atropine. In patients with signs of a sympathetic neurosis and in patients with hepatic disorders, chronaxia is unstable, it has a tendency to increase or is constantly increased. On the basis of clinical signs and of experimental observations, prolonged chronaxia is regarded as a sign of vagotonia. In exophthalmic goiter the chronaxia values are low.

Relations of Vitamins to Carbohydrate Metabolism—Schroeder investigated the relations of the most important vitamins to the carbohydrate metabolism and particularly the

action of the isolated vitamins on the disordered metabolism in diabetes mellitus. He says that a direct connection between diabetes mellitus and vitamin A is unknown. Carotene as well as vitamin A is found in the blood serum of diabetic patients, but during diabetic coma they disappeared from the blood. In view of the antagonism between vitamin A and thyroid secretion, it may be assumed that the carbohydrate metabolism is indirectly influenced by vitamin A. Vitamin B₁ has no effect on the blood sugar content. Nevertheless, a slight increase in tolerance for dextrose could be produced in diabetic patients by means of vitamin B₁. In this connection the author points out that the insulin-like action of yeast, which has been observed by several investigators, is probably due to the presence of lactoflavin, for the intravenous injection of lactoflavin reduces the blood sugar content of diabetic patients by 20 or 30 per cent. He further reports investigations on the action of vitamin B₁ and of lactoflavin on the growth and the glycogen content of various organs of rats which had B avitaminosis. Whereas the glycogen content of muscles and heart remain practically constant during the B avitaminosis, the glycogen content of the liver decreases. However, the weight as well as the glycogen content of the liver increases in these rats with B avitaminosis as soon as pure vitamin B₁ is administered by subcutaneous injection. If a mixture of vitamin B₁ and of lactoflavin is given, the result is the same. The increase in weight that can be produced by the administration of vitamin B₁ can be inhibited by the simultaneous administration of dextrose. This can be explained by the dependence of the vitamin B₁ requirements on the carbohydrate metabolism. Studies on the modification of the carbohydrate metabolism by vitamin C revealed that the injection of 300 mg of cevitamic acid regularly reduces the blood sugar of normal persons. This modification of the blood sugar content is lacking in patients with increased vitamin C requirements. The author suggests that the action of vitamin C on the blood sugar of healthy persons might be explained by the observed inhibition of the insulin antagonist thyroxine. However, this inhibition must take place indirectly, for a direct modification of the action of thyroxine by cevitamic acid proved impossible in the experiment. In elimination experiments following oral tolerance tests with 300 mg of cevitamic acid daily, it could be proved that patients with diabetes mellitus have greater vitamin C requirements than have normal persons. Observations on the blood sugar prove that the action of insulin is increased by cevitamic acid. That vitamin D is involved in carbohydrate metabolism is proved by the fact that ultraviolet irradiation effects a reduction in the sugar content of blood and urine of diabetic patients.

Wide Aorta of Congenital Origin S. Kreuzfuchs—p 1458

Chylothorax Case M. Szajna—p 1460

Anemia After Gastric Resection—Manizade points out that progress in research on anemia has proved the importance of gastric digestion for the blood and thus has corroborated the objections of internists to gastric resections. It has been asserted that the so called resection anemias may develop from five to ten years after the intervention. In order to determine the incidence of anemia after gastric resection, the author examined the blood of forty patients who from five to twelve years previously were subjected to an extensive gastric resection on account of ulcer. In the majority of patients the operation had been performed more than seven years before. The operation and the microscopic examination had demonstrated the existence of a peptic ulcer in all the patients. The patients were of various ages (from 23 to 67 years). Three of them had been operated on according to Billroth's first method all others according to Billroth's second method. All the resections had been extensive (two thirds resections). The examination

of the blood revealed in thirty-six of the forty patients that the number of erythrocytes was above 45 million, the hemoglobin values were likewise normal. Only four of the patients (10 per cent) had an anemic blood picture. Thus it may be concluded that gastric resection in patients with ulcer does not necessarily lead to anemia, although in some cases of gastric resection a predisposition together with secondary digestive disturbances may result in anemia. This possibility makes it necessary before the operation to pay attention to such factors as heredity, constitution, blood picture and gastric juice, and after the operation to watch carefully for the development of digestive disturbances and to institute promptly the proper treatment.

*Clinical Value of Epinephrine Probe Test of Muck H A E Van Dishoeck—p 5415

Clinical Value of Epinephrine Probe Test—Van Dishoeck shows that the white streak sign in Muck's epinephrine probe test is positive in a large number of cases in which a disturbance of the sympathetic nervous system exists. However, the clinical value of this test is limited by several factors: 1 By the fact that the white streak sign appears in various and rather frequently occurring disorders, thus the streak sign is not pathognomonic for a definite disease. 2 By the fact that, although the white streak sign appears in a large percentage of cases with sympathetic disturbances, it does not appear in all of them. 3 By the fact that it is elicitable in a considerable number of normal control cases. 4 By the fact that the technic is difficult and requires considerable experience. In unilateral cranial injuries, the white streak sign was often elicitable, usually on the side of the lesion. Because of this, the epinephrine probe test might be of value in the localization of cerebral process. The test is valuable also for the study of the complicated reactions of the nasal mucosa.

*Nephroptosis Its Recognition and Treatment H Mathiesen—p 1097
Sepsis in the New Born Case P N Damm—p 1112

Recognition and Treatment of Nephroptosis—Mathiesen emphasizes the importance of pyelography, especially vertical pyelography, in cases of possible nephroptosis, and prefers vertical pyelography whenever possible. He says that in suitable cases excellent results can be attained by operative treatment. The indications are grave, constant colic, affecting the patient's ability and desire to work, nephroptosis combined with beginning or developed hydronephrosis or with aberrant blood vessels or cord formation, or complications with nephrolithiasis or recurring pyelitis. The contraindications are advanced age and poor general condition due to causes other than the nephroptosis. The procedure that he now follows is to split the capsule over the lower part of the convex edge of the kidney, bring the kidney into contact with the inner side of the lowest ribs as high as possible and suture the flaps of the capsule there. The outer capsule of the kidney is often gathered about the lower pole with catgut sutures. Occasionally it is necessary to turn the kidney so that the upper pole tips slightly downward, to allow the ureter to pass from the most sloping part of the kidney. When it is difficult to raise the kidney high enough, a strip of fascia lata 15 cm wide is transplanted, after the capsule has been slit over the lower pole, the fascia is sewed fast about this and the ends are passed through an incision in the eleventh intercostal space and sutured to the edges of the wound. He considers the partial decapsulation a particularly important step in nephroptosis, as the bloody surface best assures formation of firm adhesences between the kidney and its seat. The patient must remain in bed for at least three weeks and must not for some time after discharge do heavy work. Of the author's fifty patients with nephroptosis, twenty-five were treated with nephroptosis, of these, twenty are well, two improved and two unchanged and one is dead.

In five cases the ptosis was combined with aberrant renal blood vessels. Five cases are reported. The two improved and the two unchanged patients were operated on by other methods than the one described, all patients treated by this method are well.

Irregular Glandular Hyperplasia of Endometrium Treated by Excision of Uterus K H Koster—p 1164

The Pituitary and Carbohydrate Metabolism—Lassen and Hansen state that injection of an alkaline extract of the anterior lobe of the pituitary can produce a marked diabetogenic effect both in the normal and in the diabetic organism, together with a considerable increase in ammonia elimination, the latter being presumably an expression of the presence of a ketogenic principle in the extract. The diabetogenic action is doubtful when only small amounts of protein and no carbohydrate are resorbed from the intestine. It is best demonstrated following the ingestion of meals with moderate carbohydrate and protein content. On intake of larger amounts of carbohydrate (about 75 Gm), either as pure dextrose or in a meal with abundant carbohydrate, the injection of the extract, whether intramuscularly or intravenously, cannot raise the peak of the curve, the diabetogenic effect appears in an increased width of the curve. Finally, the experiments indicate, but do not prove, that injection of extract of the anterior hypophysis can cause a transient fall of the sugar threshold of the kidneys in healthy persons with normal sugar threshold.

*Electrocoagulation of Lupus Vulgaris in Combination with Other Forms of Local Treatment V Genner—p 1109

Postoperative Tetany Treated with A T 10 Three Cases M Faber—p 1118

Therapeutic Reports from Practice V Erlendsson—p 1122
Fandoch V Halberg—p 1123

Treatment of Lupus Vulgaris—The different forms of local treatment of lupus vulgaris at the Finsen Institute are reviewed. Genner says that the Finsen treatment, given by a technically trained and competent personnel, is the main method of treatment and will under these conditions give the best results both as to recovery and cosmetically. Caustic ointment, surgical excision, diathermic excision and electrocoagulation are auxiliary methods. Regard for the cosmetic side must not be carried too far, where light treatment has not resulted in recovery after a reasonable time and recovery is believed possible, recourse must be taken to the more radical adjuvant methods named the time and the choice to be decided by the physician experienced in treatment of lupus. Electrocoagulation is a supplement that can advantageously be used in connection with light treatment, either as a preliminary treatment or later, in a limited number of cases in which other aids cannot be applied, as in order to destroy superficially isolated well defined nodules. Forty-two cases treated with electrocoagulation and observed for several years are tabulated.

PATHOLOGIC FRACTURES

RALPH K GHORMLEY, M D

CHARLES G SUTHERLAND, M D
AND

GEORGE A POLLOCK, M D

Fellow in Orthopedic Surgery the Mayo Foundation
ROCHESTER, MINN

Very little has been written on the subject of pathologic fractures. A brief but very good discussion was given by Key and Conwell.¹ Pathologic fractures are taken for granted, recognized and forgotten, perhaps justly so. Yet the question often arises whether a pathologic fracture is or is not present and the question must be disposed of before the diagnosis can be satisfactorily settled. Therefore a knowledge of pathologic fractures and of the relative importance of factors in their causation seems to us of sufficient importance to justify a review of such factors.

To this end we, assisted by Drs Galloway, Dickson, Sawyer and Rhorer, have reviewed the pathologic fractures encountered at the Mayo Clinic from Jan 1, 1924, to Jan 1, 1937, a period of thirteen years. We have found records of 660 pathologic fractures encountered in this period. For the purposes of this review we have divided these into three groups: (1) pathologic fractures attributable to metastasis from malignant lesions, (2) pathologic fractures attributable to primary malignant lesions of bone, and (3) pathologic fractures attributable to other causes, such as benign bone tumors and non-neoplastic diseases of bone.

In reviewing these cases, and particularly those of pathologic fracture from metastatic malignant growths, it was obvious that in a great number the vertebrae and ribs were affected. It is well known that many types of metastatic lesions are found in the ribs and vertebrae more commonly than in the other bones. Moreover, a careful review of these cases, and of the roentgenograms, has convinced us that these lesions produce pathologic fractures and they must be regarded as such.

We have not included any cases of tuberculosis of the vertebrae. We believe that occasionally a true pathologic fracture may occur in a tuberculous vertebra but it is so difficult to determine this fact in most cases of tuberculosis that we have not attempted to review any such cases. One case of true pathologic fracture of a clavicle, wherein tuberculosis was proved by biopsy, was included. It should be emphasized that such a condition is rare in our experience and the case is not recorded in any table accompanying this paper.

From the Section on Orthopedic Surgery (Dr Ghormley) and the Section on Roentgenology (Dr Sutherland), the Mayo Clinic.
Read before the Section on Orthopedic Surgery at the Eighty Eighth Annual Session of the American Medical Association, Atlantic City, N J, June 11, 1937.
1 Key J A and Conwell H E. The Management of Fractures Dislocations and Sprains. St Louis: C V Mosby Company, 1934.

In discussing the cases in which metastatic malignancy of various types was found, the predominance of lesions of the breast is obvious (table 1). This is as one would expect, because lesions of the breast are known to metastasize to bone frequently and pathologic fractures do occur. The greater number of these are metastases to the ribs and vertebrae, as we have already noted. However, other bones were affected, particularly those of the pelvis, the femur and the humerus. No cases in which metastasis involved the hands or feet were noted. The type of lesion is usually the so-called osteolytic type of metastatic lesion, although occasionally a lesion of the so-called osteoplastic type may be seen. In some instances in which extensive destruction of ribs and vertebrae was all that could be noted, the presence of a pathologic fracture was assumed. Any attempt to draw any actual conclusions as to the percentage of pathologic fractures in these cases seemed unwise for the obvious reason that in most cases of cancer of the breast with metastasis our observation of the patient was but for a short time. In many cases, perhaps all those in which metastasis to bone ultimately occurred, pathologic fractures also occurred. When such fractures involve the thoracic cage they may never be discovered unless carefully made roentgenograms are frequently studied, and this study is not done in most of these cases. Could all these cases have been followed through to the end and the number in which there were pathologic fractures thus determined, a fairly accurate basis for estimation of percentage might have been reached.

Of the cases designated "metastatic malignancy indeterminate" we feel that a number may have been cases of myeloma. These cases were, for the most part, those in which metastatic lesions of bone were recognized, without any discoverable primary malignancy. The patients usually were sent home without long periods of observation because it was recognized that little could be done for them. Unfortunately in few, if any, of these cases were there available reports of necropsy. On the other hand, there were in this group a few cases in which specimens of the lesion in the bone were taken for biopsy, with a resulting diagnosis of "metastatic carcinoma" or "adenocarcinoma," but in which the primary malignant growth could not be found. From the standpoint of exact etiology these cases too cannot be classified because the primary lesion in many of them never can be determined (fig 1).

The relatively small number of cases of carcinoma of the prostate gland is as one would expect. These metastatic lesions usually are osteoplastic and do not produce enough destruction of bone to lead to pathologic fracture. There may, however, be an occasional metastatic lesion of the osteolytic type, in which fractures may be found, and occasionally a fracture may be seen in a metastatic lesion of the osteoplastic type.

Metastatic lesions from hypernephromas (fig 2) always have been recognized as occurring frequently in bone metastases, and the number here noted as having produced pathologic fractures is relatively high, as the total number of cases of hypernephroma was small

TABLE 1—Metastatic Malignant Lesions Which Caused Pathologic Fracture, Jan 1, 1924 to Jan 1, 1937

Lesions	Patients Who Had Fractures
Carcinoma of breast	127
Metastatic malignancy, indeterminate	79
Carcinoma of the prostate	20
Metastatic hypernephroma	12
Carcinoma of the stomach	10
Carcinoma of the uterus	7
Carcinoma of the thyroid	6
Lymphoblastoma (including Hodgkin's disease)	6
Carcinoma of tongue and lip	5
Carcinoma of the pancreas	2
Carcinoma of the rectum	2
Carcinoma of the liver	1
Carcinoma of the sigmoid	1
Total	278

Among the remaining fractures caused by metastatic malignant lesions, the rather large number from carcinoma of the stomach should be noted. We say "rather large" because of the fact that bony metastasis from carcinoma of the stomach rarely is recognized. Of the latter group of cases, in two the diagnosis was proved by postmortem examination, in four by exploratory abdominal operation, and in the remainder the diagnosis was based on clinical and roentgenologic observations.

In reviewing table 2, which is concerned with cases in which there were primary malignant lesions of bone, the largest number of cases is represented, of course, by osteogenic sarcoma. For this paper we have included all types of osteogenic sarcoma, except endothelioma, in the one group. By this we mean fibrosarcoma, chondrosarcoma, myosarcoma and the mixed types of sarcoma. Again, we would emphasize that in many of these cases pathologic fractures may have appeared at a later date but at the time of our observation the incidence of pathologic fractures was that indicated here (fig 3).

TABLE 2—Primary Malignant Lesions of Bone Which Caused Pathologic Fractures, Jan 1, 1924, to Jan 1, 1937

Lesions	Patients with Fractures	Approximate Percentage of All Patients*
Osteogenic sarcoma	44	11
Myeloma	39	32
Endothelioma (Ewing's tumor)	23	19

* By "all patients" is meant all patients with each condition encountered. Example: Forty-four patients represent 11 per cent of all patients who had osteogenic sarcoma in the designated period.

Myeloma is of course recognized as a frequent cause of pathologic fractures. An extremely destructive lesion of bone probably always causes pathologic fractures if observed long enough. As we have already noted there may be, among the cases of metastatic malignant growths of indeterminate type, several cases of multiple myeloma. In the earlier stages the differential diagnosis often is difficult and unless Bence-Jones proteinuria is discovered, or a specimen is taken for biopsy, the diagnosis can sometimes be made only after prolonged observation, that is, repeated observations over several months (fig 4).

The relatively large number of cases of fracture associated with endothelioma of the Ewing type speaks for the destructive nature of this lesion. We have not

distinguished here between what may be primary Ewing's tumors and what may be metastatic lesions of the same type. Most of the pathologic fractures apparently occurred in primary lesions (fig 5).

Turning to the benign lesions which caused pathologic fractures (table 3), the largest group is what we call senile osteoporosis. This represents an entity which is now fairly readily recognized. The exact nature of the lesion, in our opinion, never has been accurately described. Schmorl² has given an accurate description of the pathology of this condition, pointing out that there are two essential conditions: first, compression fracture and, second, ballooning of the disks, which is made possible by softening of the vertebrae. To the resulting misshapen vertebrae he has given the name of "fish-tail vertebrae." Schmorl stated that there are various etiologic factors: different disturbances of nutrition, changes in mode of living or of the internal secretion and constitutional anomalies.

Judging from our observations, patients who have senile osteoporosis usually have complained of severe back pain. Often the onset has followed a slight injury.

TABLE 3—Benign Lesions Which Caused Pathologic Fractures Jan 1, 1924 to Jan 1, 1937

Lesions	Patients with Fractures	Approximate Percentage of All Patients
Senile osteoporosis	92	81
Osteitis fibrosa cystica	32	46
Giant cell tumor	2	21
Osteogenesis imperfecta	2	100
Osteomyelitis	2	1
Paget's disease	20	8
Bone cyst	11	10
Fibrosarcoma	12	0.5
Chondroma	11	4
Osteoporosis of disease	6	
Hyperparathyroidism	4	93
Osteomalacia	4	13
Hemangioma	3	
Total	269	

* By "all patients" is meant all patients with each condition encountered. Example: thirty-two patients represent 46 per cent of all patients who had osteitis fibrosa cystica in the designated period.
† Percentage based on count of all cases of osteoporosis.

and in many instances there have been several injuries. Some round back deformity often develops and gradually may increase until, in some instances, the stature becomes shortened. There is usually some degree of muscular spasm which may, in time, become very marked, in many instances the disability becomes great, some of the patients becoming bedridden. The lower age limit is usually 50 years, most of the patients are more than 60. However, we have seen at least one patient whose age was less than 40 years.

The characteristic roentgenographic picture in senile osteoporosis is diffuse osteoporosis, particularly of the vertebrae and pelvis, with compression fractures and ballooning of the intervertebral disks. The number of such compression fractures varies with the extent and severity and probably with the duration of the disease, as well as with the incidence of injury.

Many patients with senile osteoporosis have been suspected of having parathyroid tumors and exploratory operations have been performed without such tumors being found. However, as time goes on and experience accumulates, the differential diagnosis between this condition and the parathyroid tumor osteitis of von Recklinghausen is fairly simply made. In senile osteoporosis there is not any significant change in the chemical elements of the blood. Definite associated disease cannot

2 Schmorl, Georg. Die Gesunde und Kranke Wirbelsäule 172. B. gebild. Leipzig: Georg Thieme, 1932.

be found consistently. One can quiz such patients regarding diet and usually can convince oneself of a deficient intake of calcium. However, we feel that probably in many persons who are deficient in intake of calcium this disease never develops. Many important facts regarding this condition are yet to be determined.

The importance of senile osteoporosis as a clinical entity is evident at least in the fact that in this series

Fig 1.—Pathologic fracture in a case of metastasis from a carcinoma of the thyroid

of cases except for metastasis from carcinomas of the breast it was the most common cause of pathologic fractures. That it produces disability, often severe enough to make the patient an invalid, is obvious. Many patients are less severely disabled but in all cases the disability is pronounced and pain is persistent when the patient is up and about.

Usually the pain of senile osteoporosis is relieved by rest. In our experience, the condition of many patients has been improved by persistent use of a diet high in calcium or by administration of calcium, together with some form of vitamin D. At the same time, we have used a Taylor brace or heavily stayed corset to support the spinal column. Such treatment must be kept up for many months to accomplish any improvement. The subjective improvement has been more striking than the objective improvement is oftentimes in spite of apparently genuine subjective improvement little evidence of actual improvement is to be found in the roentgenograms.

We find that next to the largest group of these bony lesions is osteitis fibrosa cystica. It is not our purpose to discuss the differential diagnosis of osteitis fibrosa cystica, von Recklinghausen's type of osteitis fibrosa which we have here designated as hyperparathyroidism, giant cell tumor and bone cyst. We admit the difficulty in this differential diagnosis at times. In this series we have attempted to group them as indicated. Among those lesions designated as osteitis fibrosa cystica are for the most part the multiple lesions usually found in childhood. Such lesions often involve the shafts of the long bones sufficiently to cause weakness such that fractures are easily incurred.

Giant cell tumors often are causes of pathologic fractures. One who is familiar with this lesion knows that as they increase in size they often cause thinning of the cortex to the point at which pathologic fracture is inevitable. Occasionally the portion of a joint surface adjacent to the lesion may cave in and produce a fracture.

In considering osteogenesis imperfecta we have not attempted to distinguish the variously designated causes of brittle bones such as osteopetrosis, fragilitas ossium, brittle bones and blue sclerae, and osteogenesis imperfecta. To us it seems that the dividing line between any two of these groups is not clearly defined and for purposes of this presentation the lesions can be grouped as one. The underlying cause may be that described by Key,³ namely, hereditary hypoplasia of the mesenchyme. This seems to us the most logical concept when the pathologic picture is considered. From the standpoint of this paper, the important thing to realize is that probably, in all these cases, at some time or other pathologic fractures occur. Our patients did not all present themselves at the time when fracture occurred but all gave histories of having had fractures at some time.

In the presence of osteomyelitis, fractures are often hard to recognize. There are in general two types of pathologic fracture in these cases, namely, those that result from extensive destruction of the bony cortex

Fig 2.—Pathologic fracture in a case of metastasis from a hypernephroma

and those that occur as a result of weakening of the bone by surgical removal of bone. The former group is by far the largest (fig 6). The possibility of post-operative fracture must always be considered in cases of osteomyelitis and proper support must be given when extensive surgical procedures are performed.

³ Key, J. A. Brittle Bones and Blue Sclera. *Arch. Surg.* 12: 523, 567 (Oct.) 1921.

Paget's disease is not often recognized as a cause of pathologic fracture but among our cases we found twenty in which the fracture seemed unquestionably pathologic. That weakening of the bone by the disease may reach the point at which a pathologic fracture may occur is obvious, that such fractures do not occur more often may be unusual.

Fig. 3—Pathologic fracture in a case of osteogenic sarcoma.

Bone cysts, just as osteitis fibrosa cystica and giant cell tumors, cause so much thinning of the cortex of the bone that fractures may easily ensue. Usually the fracture occurs with little or no strain or force, just a slight twist or throw of the extremity will produce the fracture. When the cysts are large, the best results usually are obtained by operation and bone graft. Some smaller cysts undoubtedly will heal with diminution of the size of the cyst after a pathologic fracture. With the larger ones, however, collapse of the bone usually is not a sufficient stimulus to formation of bone to promote complete healing of the cyst.

Tabes dorsalis long has been recognized as a cause of pathologic fracture. Just what the underlying pathologic condition is in these cases never has been determined. We recognize the fact that diminished sensation is commonly found but this alone does not seem to be sufficient. Whatever there is in the character of this bone which leads to Charcot joints probably leads also to pathologic fracture, for there is much similarity between the two processes.

The majority of chondromas which lead to pathologic fractures are those of the phalanges and metacarpal or metatarsal bones. Such chondromas are often diagnosed as cysts, but in several cases of this group the lesion was excised and was replaced by bone grafts. In nearly all instances the diagnosis proved to be chondroma. Thus it may be said that any pathologic fracture which occurs through an apparently cystic lesion in a phalanx or metacarpal or metatarsal bone may well be considered a chondroma until it is proved

otherwise. Pathologic fractures of the larger bones in the presence of the common type of osteochondroma are exceedingly rare. They may occur, however, in association with the so-called enchondroma wherein the tumor is largely within the cortical bone.

Osteoporosis of disuse is well recognized as an occasional cause of pathologic fractures. The number of cases in table 3 seems small, and it is likely that we have failed to gather all cases. Such fractures may occur whenever long disuse of a limb has produced a sufficient amount of disuse atrophy. The fractures are often subperiosteal or of the greenstick type and thus they may not be recognized.

Hyperparathyroidism, or osteitis fibrosa of the von Recklinghausen type, has come to be recognized as a clinical entity and may produce pathologic fractures in the more advanced cases. Often the loss of calcium is so great that clear roentgenograms are nearly impossible to obtain.

Osteomalacia when the term is strictly limited to lesions of pregnant or lactating women, represents a small group in our experience. Recognition of the disease in these instances probably is not difficult. To us it seems that there may be some relationship between this condition and senile osteoporosis. In osteomalacia one usually sees a marked deformity of the pelvic bones. The Looser zones which are seen in this condition are probably not pathologic fractures but defects in ossification, or regions in which there is absorption of the osseous substance of the bone. The zones usually are symmetrical.

Hemangiomas, in our cases, were all of the vertebrae. Such a lesion of the vertebrae has been fairly

Fig. 4—Pathologic fracture in a case of multiple myeloma.

accurately described and usually it is recognized by roentgenologists as a fairly typical lesion. In none of these cases has biopsy been done to prove the identity of the lesion but they were all rather typical. Pathologic fractures may occur when the lesions are far advanced, usually the fracture is of the compression type and does not cause much injury.

Remaining to be mentioned are one case each of neurofibroma, post-irradiation osteitis, pituitary basophilism, purpura haemorrhagica, transverse myelitis, neurocytoma and tuberculosis. The last case was mentioned early in this paper. Fracture following irradiation for a malignant condition of the pelvis is deserving of comment. There may be more of these cases among

Fig 5—Pathologic fracture in a case of endothelioma (Ewing type)

our cases in which there is a malignant condition of the pelvis than we have encountered in this study. The whole subject has been well presented in a paper by Dalby, Jacob and Miller.⁴ Their description of the underlying pathologic condition leaves a little doubt as to the actual nature of the lesion but the etiologic factor seems to be well founded. The compression fracture of a vertebra which occurred in a case of pituitary basophilism may have been purely on a basis of osteoporosis. The case in which the fracture was attributable to purpura haemorrhagica was most unusual. A huge tumor of the thigh developed after an injury, with fracture and subsequent marked absorption of bone. Exploration of the tumor by hollow needle disclosed the presence only of blood clot. The presence of a general blood dyscrasia was recognized and a diagnosis of purpura haemorrhagica was made. Splenectomy was advised but the patient refused operation and subsequently there has been little change. We believe the condition of the bone to be the result of an unusual type of pressure erosion, however, probably incidental to the blood dyscrasia.

We have tabulated and briefly reviewed the cases of pathologic fracture seen at the Mayo Clinic over a period of thirteen years. The relative importance of various diseases as causes of pathologic fractures is obvious in the tables. As an aid to diagnosis of a case, when a pathologic fracture is the presenting lesion, these tables may be of some help.

ABSTRACT OF DISCUSSION

DR JOSEPH A. FREIBERG, Cincinnati. In this comprehensive discussion of pathologic fractures Dr Ghormley and his associates have brought to our attention a subject which is often considered unworthy of serious study. It is my impression that when a pathologic fracture is found, too frequently it is decided by the physician in charge that the patient's days are numbered and he is made comfortable by splints and medication and not adequately studied. In this group of orthopedic surgeons it is realized that the presence of a pathologic fracture should stimulate one to thorough study of the case because in many of these cases we can be of great assistance. The authors have

shown that the patient may have from one to many years of comfort and often physical activity. The group of cases of senile osteoporosis has interested me because I have seen a great number of them and because they are not recognized as frequently as they should be by the general practitioner. The picture of an older person gradually losing height and developing a severe dorsal kyphosis is accepted as undergoing changes of old age. The fact that the patient may have severe localized pain in the back is not considered or studied sufficiently.

DR PHILIP LEWIN, Chicago. I was impressed with the large number of cases presented, 660 cases in thirteen years. The authors have covered every angle of the subject. I was impressed with the large percentage of primary tumors outside the usual ones, such as tumors of the breast, uterus, thyroid, prostate and adrenal, that is the large number that occurred in the gastro-intestinal tract or the liver, pancreas, stomach or intestine. I am sorry the authors did not get a chance to talk about their cases of Paget's disease. I remember one woman with Paget's disease who did not know she had the disease, until she had a pathologic fracture. At open operation I applied hard rubber strips as splints and maintained their position by Putti bands. She obtained perfect consolidation. These fractures have been called greenstick fractures which they are not, as can be seen from the pictures. Codman's term rotten wood fracture is certainly better than the other. I was interested in the cases of osteogenesis imperfecta having a patient who is about 50 years of age, which is quite an advanced age for these patients. Her height is 37 inches (94 cm). She has had 112 fractures but is now teaching in a school for crippled children. I was glad that the authors presented some cases of senile osteoporosis and that Dr Freiberg discussed them. I have had a number of cases in an interesting group in which there was pain in the lower part of the back, the middle of the back and high in the back, but especially in the middle and lower part of the back where a combination of proper bracing following bed treatment and large doses of calcium intravenously

Fig 6—Pathologic fracture in a case of osteomyelitis

combined with either roentgen or radium irradiation, was followed by complete relief.

DR RALPH K. GHORMLEY, Rochester, Minn. The subject, as Dr Freiberg said is one that is oftentimes more or less forgotten but so many of these cases come to us with a fracture as the primary lesion that a little more ability in recognizing the type of pathologic fracture might be of help in proper diagnosis and the institution of proper treatment.

LESIONS OF THE BRAIN FOLLOWING FEVER THERAPY

ETIOLOGY AND PATHOGENESIS

F. W. HARTMAN, M.D.

DETROIT

In 1935 the literature related to the pathologic changes incident to exposure to heat was reviewed and the lesions produced by accurately controlled fever therapy in two human beings and twenty experimental animals were reported.¹ Briefly the pathologic changes noted may be summarized as follows. Gross changes consisted of engorgement and congestion of blood vessels, degeneration and hemorrhage of the adrenals, hemorrhages in the brain, marked edema and congestion of the lungs, contraction and bloodlessness of the intestine and parenchymatous degeneration of the liver and kidneys. Microscopically, acute passive congestion of all the organs and tissues and cellular degeneration and hemorrhages of varying degree in the adrenals, liver, brain, lungs and kidneys were visible.

At the time of the previous report no attempt was made to determine the etiology and the pathogenesis of the lesions described; it was assumed that they were due to the heat applied, and it was pointed out that the use of certain groups of analgesic drugs seemed to be a contributing factor.

When I reviewed the monograph of Courville, "Asphyxia as a Consequence of Nitrous Oxide Anesthesia," the striking parallelism between the lesions of the brain which he ascribed to asphyxia and those observed after fever therapy suggested that asphyxia or anoxia was at least one of the factors in the causation and development of the pathologic changes associated with exposure to heat. This suggestion immediately raised the following questions:

✓ 1. Is this apparent parallelism confirmed or disproved by histologic examination of the brain and other organs?

2. Are the physical and the biochemical disturbances associated with fever therapy conducive to anoxia?

3. Does anoxia occur during fever therapy and if so to what degree?

This study was undertaken in an effort to answer these questions.

MATERIAL

In addition to a review of the two cases (cases 1 and 2) and the experiments on twenty animals previously reported, one more case and experiments on fifteen animals are included in this study.

CASE 3—History.—W. L., a white man aged 31, first seen on July 23, 1934, had been having periodic attacks of iritis for the past two years. One year previous to the onset of iritis he was confined to bed for several weeks with streptococcal sore throat. The general physical examination showed nothing significant except marked sensitivity to *Streptococcus viridans* (stock vaccine) and to nonhemolytic streptococcus obtained from stool culture. The tuberculin test was negative until 0.1 mg. of old tuberculin was used. (At another clinic the patient later gave a marked reaction to 0.001 mg. of old tuberculin.) Serologic examination gave negative results. Examination of the eyes revealed marked bilateral iridocyclitis.

From the Department of Pathology, Henry Ford Hospital.
Read before the Section on Pathology and Physiology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

1. Hartman, F. W., and Major, R. C. Pathological Changes Resulting from Accurately Controlled Artificial Fever. *Am. J. Clin. Path.* 5: 392 (Sept.) 1935.

caused, it was thought, by a systemic bacterial infection. That it was a tuberculous process was also considered possible.

Treatment consisted of injection of autogenous vaccine and tuberculin, plus local medication to the eyes. The response was indifferent.

Beginning July 8, 1935, the patient was given a series of six fever treatments at intervals of from four to seven days for five hours each, with the temperature varying from 103.2 to 107.4 F. Sodium amytal and pantopon (the hydrochlorides of the alkaloids of opium, principally morphine) were the sedatives used in five treatments and paraldehyde in the sixth. After these treatments the condition of the eyes improved temporarily. The patient was given a rest period until March 3, 1936, when he was given another series of fever treatments. The intervals between treatments were from five to seven days, except that between the last two treatments which was thirteen days. The first five treatments each lasted five hours and the temperature ranged from 104.8 to 107.6 F. The sixth treatment lasted six hours, and the temperature ranged from 105 to

Fig. 1 (case 3).—Section from the cortex under medium power showing unusually wide perivascular spaces and distorted, shrunken and pyknotic pyramidal cells.

107.2 F. Sedormid (allyl-isopropyl-acetyl- γ -tributamide) and pantopon were the basic sedatives except during the last treatment in which 5 grams (0.3 Gm.) of pantopon and 1½ grams (0.1 Gm.) of pentobarbital sodium were given.

The patient tolerated the first thirteen treatments quite well although he had some nausea and vomiting. The blood pressure was 114/60 at the beginning of the last treatment and 68/20 at the conclusion. At 9 p. m. he was comfortable, the blood pressure was 90/68. At 6:30 a. m. the following morning, he became apneic and was given artificial respiration and supportive treatment with some improvement. At this time the left pupil was dilated, respiration was stertorous and all deep reflexes were absent. At 10 a. m. his condition was unchanged. The blood pressure was 142/85, the color good, the right side of the face weak, the limbs flaccid and the deep reflexes active and equal. The carbon dioxide combining power was 35.3 per cent. The patient died at 1:45 p. m. twenty hours after his last treatment. The clinical diagnosis was cerebral hemorrhage.

Necropsy—The body was well nourished and well developed. The skin was livid and congested. The lips and fingernails showed marked cyanosis. The peritoneum was smooth and the abdominal organs of the usual size. The pleural cavities were free from fluid and adhesions. The thymus gland had two lobes measuring 8 by 5 by 1 cm. The pericardial sac contained 25 cc of clear fluid.

The heart weighed 300 Gm. Numerous small petechial hemorrhages were seen throughout the epicardium. The valves were intact throughout. The coronary vessels were patent. The left lung weighed 350 Gm and the right 400 Gm. The pleural surfaces were smooth. The parenchyma in the upper and the middle lobe of the right lung were air containing. The lower lobes were increased in density, dark reddish brown and atelectatic. On section through the lower lobes much bloody fluid was expressed on pressure, but no air.

The spleen weighed 185 Gm. The pulp was soft and the lymphoid tissue abundant. The liver weighed 1580 Gm. The capsule was smooth and the parenchyma reddish brown. The usual architecture was well preserved. The gallbladder emptied readily. The walls were of the usual thickness and the mucosa intact. The pancreas was of the usual size, firm, distinctly lobulated and grayish pink. The adrenals were of the usual size and shape. On section the cortical tissue was seen to be light grayish yellow, white and the medulla well preserved and dark brownish yellow. The left kidney weighed 125 and the right 120 Gm. The cortical surface was smooth, the cortex measuring from 5 to 7 mm, and the usual architecture well made out. The urinary bladder contained 500 cc of clear urine. The prostate was of the usual size. The stomach was markedly dilated with fluid and gas. The mucosa was intact. The remainder of the gastrointestinal tract was not remarkable.

The calvarium was of the usual thickness. The pia and the arachnoid were delicate and glistening. The convolutions were broad and flat while the sulci were narrowed. The right lobe of the cerebellum was a soft hemorrhagic necrotic mass. There was marked molding of the cerebellar peduncles. Minute examination of the vessels in the circle of Willis showed no abnormalities and no evidence of thrombi or emboli. Bacteriologic examination showed no growth.

Microscopic Examination—The thymic parenchyma was well preserved with the usual small lymphoid type of cell and Hassel's corpuscles in abundance. There was little fatty tissue. Sections from the myocardium showed muscle fibers of average size and shape and no evidence of degeneration. In sections from the lower lobes of the lungs alveoli were filled with fluid and blood. The bronchioles in the same areas showed polymorphonuclear leukocytes. The architecture of the spleen was usual but there was an unusual amount of yellowish brown blood pigment. The mucosa of the intestine was intact and without evidence of hemorrhage. The pancreas contained the usual number of islands of Langerhans which were well preserved. The cytoplasm of the liver cells was granular and the nuclei were pyknotic. The sinusoids were engorged. The adrenals showed marked hyperemia but no hemorrhage or necrosis. The tubular epithelium of the kidneys contained much granular degeneration and pink-staining amorphous material. The glomerular tufts were hyperemic but no hemorrhage was seen.

Sections from the cerebrum showed marked edema with unusually large clear spaces about the smaller vessels and about many of the pyramidal cells. The pyramidal cells themselves in many instances took the stain poorly. The nuclei were broken up and the Nissl bodies could not be made out. Sections from the cerebellum in the better preserved left lobe showed marked congestion and some diffuse hemorrhage. The Purkinje cells were poorly staining and the nuclei pyknotic. In the right necrotic lobe the tissue took a homogeneous pink stain although nuclei here and there stained poorly. There was extensive hemorrhagic infiltration. No evidence of thrombosed or occluded blood vessels could be made out.

Anatomic Diagnosis—The diagnosis was acute iritis with loss of vision, necrosis of the right lobe of the cerebellum with hemorrhage, edema and congestion throughout the cerebrum and

cerebellum, degeneration of cell groups throughout the cerebrum and cerebellum, especially of the pyramidal and Purkinje cells, atelectasis and hemorrhage (hemorrhagic pneumonia) of the lower lobes of both lungs, old calcified tuberculosis of the left lung, dilatation of the stomach, parenchymatous degeneration of the liver and kidneys.

ANIMAL EXPERIMENTS

The technic of the animal experiments was similar to that previously reported. The temperatures induced ranged from 104 to 108 F and the duration from four to fourteen hours. When the animals were removed from the Kettering hyperthermia, arterial and venous blood was obtained immediately under oil, by incision and puncture of the femoral vessels, for examination of the oxygen saturation. When the animals died or were killed autopsy was done at once and tissues for microscopic examination were placed in 10 per cent solution of formaldehyde.

Fig. 2.—Section under medium power from the base of the brain of the animal described in the representative protocol showing widely dilated perivascular spaces and poorly staining shrunken Langhans cells and necrosis.

REPRESENTATIVE PROTOCOL

A bitch weighing 16 Kg with a rectal temperature of 102.4 F was given 12 grams (0.8 Gm) of sodium amytal intraperitoneally and placed in the hyperthermia at 9:15 a.m. The temperature of the cabinet was 165 F and the humidity 45 per cent. After an hour and twenty-five minutes of treatment the rectal temperature had risen to 104.6 F. At this time 3 cc of paraldehyde was given by stomach tube. The rectal temperature was 107.2 F at 1:30 p.m. averaging 105 F throughout the five and a quarter hours of treatment. Physiologic solution of sodium chloride was given freely by mouth throughout the treatment. On removal the animal was in good condition with rapid respirations and a strong bounding pulse. The wrappings were left in place. With procaine hydrochloride anesthesia the femoral vessels were exposed and blood was removed under oil from both artery and vein. Examination of the arterial blood showed an oxygen content of 15.59 volumes per cent in oxygen capacity of

26.65 volumes per cent and an oxygen saturation of 59 per cent. Examination of the venous blood showed an oxygen content of 11 volumes per cent and an oxygen saturation of 41 per cent. The wrappings were left in place until 11 p. m., but the temperature remained elevated and was 106 F (rectal) when the animal died at 9 a. m. the following morning.

The autopsy, begun at 9:20 a. m., showed marked edema and hemorrhagic consolidation of the lungs, marked engorgement of

lightly staining and pointed. In the human beings and in the animals surviving for a longer period, the same type of cells (cresyl violet stain), especially the cytoplasm, stained lighter, and the chromidial substance was pushed to the periphery, clumped and lightly staining. The nucleus was small and pyknotic. This group showed also many small rounded spaces throughout the base of the brain, indicating the degeneration and loss of individual cells.

The necrosis of whole groups of cells and their glial tissue, referred to as "devastation areas" by Gildea and Cobb,³ was a characteristic lesion in the human brains involving the base in two and one lobe of the cerebellum in the third (figs. 3 and 4). Further, the animals that survived twenty-four hours or longer showed similar but less extensive lesions. This massive necrosis was accompanied by hemorrhage in all instances, being most striking in the human brains.

The minute cellular changes and the areas of necrosis observed in these brains after fever therapy are the histologic changes observed after cerebral anoxia produced by ligation of blood vessels, carbon monoxide poisoning and asphyxia.

Are there physical and biochemical disturbances associated with fever therapy conducive to anoxia? As pointed out by Barcroft,⁵ anoxia is produced by alterations in both the supply and the utilization of oxygen, and it is only with these alterations in mind that one

Fig. 3 (case 1)—Section from the base of the brain under low power showing a large area of devastation necrosis.

all tissues and outspoken hemorrhage throughout the brain. All the histologic changes detailed hereafter were exaggerated as compared with those in the other animals studied.

COMMENT

Is the apparent parallelism between the pathologic changes due to fever therapy and those due to anoxia confirmed or disproved by histologic examination of the brain and other organs? The perivascular spaces and the perineural spaces of the brain in all three cases of fever therapy and in the brains of all the animals which survived the fever therapy were unusually wide when compared with those of controls (fig. 2). This condition was reported by Courville,² Gildea and Cobb,³ Landis,⁴ and others, as resulting from anoxia produced in various ways both clinically and experimentally. All investigators agree that cerebral edema is a constant effect of anoxia in the brain. Landis,⁴ by demonstrating that fluid passes through capillary walls at four times the normal rate after only three minutes' lack of oxygen furnished the probable explanation.

In animals surviving for only a few hours after the completion of fever therapy, the most characteristic change seen in the pyramidal ganglion and Purkinje cells was distortion, shrinkage and homogeneous dark staining. In addition, the processes were shrunken

Fig. 4 (case 3)—Section from the cerebellum under low power showing necrosis, extensive hemorrhage and shrunken pyknotic Purkinje cells.

can deal with the problem to the best advantage. Hence the following definitions (Peters and Van Slyke⁶):

I. Anoxic anoxia. If there is a deficit in the arterial oxygen tension at which the blood delivers oxygen to the cells, the cells are compelled to work at a lower pressure.

2 Anemic anoxia The same result follows if, because of lack or inactivation of hemoglobin the volume percentage of oxygen that can be carried by the arterial blood is low, in this case removal of the usual volume percentage of oxygen from the blood by the cells is accomplished by an abnormally great fall in tension

3 Stagnant anoxia Even when the arterial blood has an entirely normal oxygen content and pressure anoxia in the cells occurs if the circulation is so retarded

that the oxygen is not transported rapidly enough to maintain its optimum tension in the active tissues

4 Histotoxic anoxia With the supply of oxygen perfectly normal in all respects, anoxia may nevertheless occur if the tissue cells are poisoned in such a manner that they cannot use the oxygen properly

Early biochemical studies⁷ showed that alkalosis occurs soon after pyretotherapy is begun, the p_{H} of the blood averaging 7.6 and the carbon dioxide combining power being reduced to 40 volumes per cent. This results from the rapid breathing and blowing off of carbon dioxide. If at the same period the respirations are shallow, little fresh air gets into the alveoli of the lungs because of the dead space in nose, trachea and bronchi, and the result is decreased oxygen saturation of the arterial blood. The alkalosis is important, since the slightly alkaline hemoglobin compound gives up its oxygen less readily to the tissues than normal hemoglobin.

Another contributing factor is the increased temperature of the blood, which Barcroft⁸ has shown decreases the oxygen saturation. The same increase in temperature increases the basal metabolic rate (Simpson⁹) 55 per cent for each degree giving a rate of +40 per cent with a temperature of 106° F. Increased metabolism means a corresponding demand for oxygen in the tissues.

Merkins and Davies¹⁰ found the rate of local blood flow through the capillaries so rapid when the arm is placed in hot water that there is little difference in

oxygen saturation between the arterial and the venous blood. Kissin and Bierman,¹⁰ Tenney¹¹ and Bazett¹² found that the velocity of blood flow increases during fever therapy. Figures from this series of nineteen experiments show that there is less difference in oxygen saturation between blood from the femoral artery and blood from the femoral vein after fever therapy than in the normal subject. The oxygen unsaturation of the tissue gradually mounts as long as the propelling force responds. If this force is indicated by rapid weak pulse and falling blood pressure, the accelerated velocity of the blood may be replaced by comparative stagnation in the dilated vessels resulting also in oxygen unsaturation because the transportation is too slow to maintain the optimum oxygen tension in the tissues.

As noted in earlier communications,¹³ the type of sedative used seems to have a bearing on the percentage of cyanosis, vascular and respiratory collapse and mortality. Keilin¹⁴ has shown experimentally that cyanide, alcohol, acetone and ethyl urethane stabilize the oxy-cytochrome of the tissues so that oxygen is not readily removed. More recently the English workers Jowett and Quastel of Cambridge University¹⁵ have shown that phenobarbital, chlorbutanol and evipan (evipal soluble) decrease or abolish oxygen utilization by the brain. The administration of oxygen during fever therapy in the series here reported tended to reduce the sedative effect of sodium amytal. Enough separate factors tending to produce anoxia during fever therapy to justify an affirmative answer to the second question have been presented.

Does anoxia occur during fever therapy and if so to what degree? The answer to this third question is found in tables 1 and 2.

TABLE 2—Normal Animals

Date, 1937	Number	Duration of Treatment Hours	Temperature F		Arterial Blood			Venous Blood Oxygen Content Volumes per Cent	Comment
			Beginning	End	Oxygen Content Volumes per Cent	Oxygen Capacity Volumes per Cent	Oxygen Saturation Percentage		
5/19	1				21.03	24.40	87.0	18.40

the arterial blood decreased to below 65 volumes per cent, and all died shortly after the completion of therapy.

Table 2 shows the oxygen saturation of the arterial blood in normal animals, the effect of sodium amytal and the effect of the administration of oxygen during fever therapy. Sodium amytal in common with other sedatives apparently affects the cells directly, decreasing their utilization of oxygen, and has a selective action on the brain, since the oxygen saturation of the femoral artery is normal. The oxygen saturation of the arterial blood may be kept at normal levels by the continuous administration of oxygen during fever therapy.

SUMMARY AND CONCLUSIONS

1 Constant and severe anoxia is shown by the decreased oxygen saturation of the arterial blood and the low oxygen content of the venous blood in animals after fever therapy. Animals having a saturation below 65 volumes per cent died.

2 Factors producing anoxia during fever therapy are alkalosis, accelerated blood flow, increased temperature of the blood and increased demand for oxygen in the tissues. The last results from the increased metabolism and the depressed utilization of oxygen of the tissues, especially the brain, due to the histotoxic effect of the sedatives used.

3 The pathologic changes resulting from fever therapy are typical of anoxia produced in other ways, such as prolonged asphyxia, carbon monoxide poisoning and acute alcoholism.

4 Anoxia may be prevented by the administration of oxygen throughout fever therapy, provided respiration and blood pressure are maintained at reasonable levels.

5 The best method of administering oxygen during fever therapy is the nasal catheter, it allows the patient to ingest fluids, an electric fan to be used, ice to be applied to the face and the patient to be moved. Combinations of oxygen and carbon dioxide may be used to counteract the alkalosis and apnea.

ABSTRACT OF DISCUSSION

DR. WALTER M. SIMPSON, Dayton, Ohio: During the past six years my associates and I have subjected some 800 patients to about 25,000 hours of artificial fever therapy. With the exception of one patient with fulminating meningovascular syphilis and rapidly progressive blindness who was treated with full knowledge of the grave risk involved and who died thirty-six hours after a single short treatment, no deaths have occurred that could be attributed to the artificial fever treatment. All of our patients have been subjected to a thorough diagnostic survey by the physicians in the Department of Fever Therapy Research to determine their eligibility for fever therapy. Special studies are made of the cardiac, vascular and renal functions, including electrocardiographic studies, basal blood pressure determinations, renal function tests and blood chemical analyses. It is our practice to determine the individual patient's tolerance for artificial fever therapy by giving a short trial treatment before undertaking a course of treatments requiring high temperature levels over a long period. This report again emphasizes the fact that artificial fever therapy by physical means is not a simple undertaking. In the hands of unskilled or unscrupulous persons it is fraught with danger. Even in the hands of skilled workers as in the present instance, occasional accidents have occurred. There is urgent need for fundamental studies of the type described by Dr. Hartman in order that the margin of safety may be widened. We have described our observations which indicated that fever produces varying degrees of alkalosis largely because of the loss of the important acid ions of the blood and tissues, carbonic acid and chlorides. Chloride balance can be maintained by adequate chloride intake before, during and after

the fever treatment. Dr. Hartman's studies point to a simple and practical method to combat the loss of carbonic acid and the decreased oxygen saturation. It seems apparent that artificial fever therapy by physical means should be restricted to institutions in which the physician and nurse personnel has received adequate preliminary training. Moreover, the likelihood of success in this work is greatly enhanced if it is done by physicians and nurses who devote full time to it. To give only occasional treatments in a haphazard manner is to invite disaster. The production of effectual artificial fever is not adaptable to ordinary office practice. Unless these precautions are exercised this important adventure in therapeutics is almost certainly doomed to a period of discredit not unlike that which followed the introduction of roentgen rays. In the hands of skilled and devoted workers this form of therapy seems destined to occupy an increasingly important place in the therapeutics of several diseases which have not yielded to other forms of treatment.

DR. J. M. NIELSEN, Los Angeles: I have had the privilege of examining all the patients that Dr. Courville studied and seeing the pathologic specimens. There are certain marked differences between the pathologic condition demonstrated by Dr. Courville as anoxia and the pathologic condition demonstrated by Dr. Hartman. Clinical conditions due to nitrous oxide anoxia were anoxia, the patients did not have this pathologic condition unless they lived for a considerable time. It took a number of days for it to develop. Whereas if I understand the presentation correctly, the patients died shortly afterward and had acute changes—these changes were present immediately. Also in the pathologic specimens of Dr. Courville the lesions were gross. One could look through a slide with the naked eye and see the areas of necrosis, whereas in those demonstrated here a microscopic examination was necessary. I should like to ask Dr. Hartman how long the fever was maintained in the human cases. I notice that it was maintained over many hours in the dogs. I have had experience with artificial fever therapy in dementia paralytica and in tabes and I have been bothered by one's inability to carry out many of the accurate physiologic preventive measures because one is dealing with mental patients who cannot cooperate. One has to tie them down hand and foot and make them stay there. One can give them saline solution to start, but one can't give them whatever one likes during the treatment. One patient had a rectal temperature of 108.7. I intended to stop the fever at 107 but it wouldn't stop. The patient survived and got more benefit out of that treatment than any other that was given him. Two other patients had a temperature of 108 for the same reason; it wouldn't stop. It has been necessary to put the patients in ice packs to bring the temperature down and nurse them along for twenty-four hours yet they made good therapeutic recoveries. So there are definite differences here and if the author can add more information I shall be glad to have it.

DR. VIRGIL H. MOON, Philadelphia: There is no question that heat above a certain level will cause disturbances of circulation which originate primarily in the capillaries. These are the most delicate structures in the human body. They are the most susceptible to injurious agents or to adverse conditions of various kinds. Even so mild an agent as temporary anoxia of a local area was shown by Landis to increase the capillary permeability in that area seven times. The same results followed when mild injurious agents of a chemical nature were introduced. Heat is another of the agents that will cause capillaries to lose their tonus and to relax in such a fashion as to upset the circulatory efficiency. The changes which Dr. Hartman has described are identical with the changes which I have seen in animals and in human beings in shock induced experimentally or occurring clinically. There were the same edematous congested conditions of the viscera and the same type of hemorrhages and degeneration both in the brain and in the parenchymatous organs. I am sure that he has observed a circulatory effect produced by hyperthermia which is identical in its character to the circulatory changes which I have observed when shock was induced by experimental means. And again I believe that probably oxygen therapy is one of the important agents that may be used to counteract this type of circulatory disturbance if it can be applied before the vicious cycle has progressed to the point at which the changes are irreversible.

DR CLADE BROOKS, New Orleans What is the purpose of using amylal or other barbituric acid compounds, and what amount of toxicity and mortality is due to the use of these compounds?

DR FRANK W HARTMAN, Detroit In answer to Dr Nielsen's discussion, some of the data have been misinterpreted probably because of the hurried presentation None of the pathologic lesions presented occurred in animals surviving the fever application less than twenty-four hours Most of the experimental animals lived from forty-eight to ninety-six hours after the fever The patient presented lived eighteen hours after the completion of the fever therapy and this was the last of a series of treatments The work reported is in accord with Courville's in that the longer the patient or animal lives after the anoxia the more pronounced the pathologic changes In our patients the hemorrhages and the necrosis of the cerebellum were obvious in the gross Regarding Dr Moon's remarks I am sure he feels as I do that the underlying etiologic factor in the lesions presented is anoxia With his extensive investigation of shock he recognizes as I do the importance of anoxia in the whole syndrome In answer to Dr Brook's question, the effects of the barbiturate group of sedatives has been emphasized in a previous communication In an article now in press concerning the preparation of patients for fever therapy, Dr Dowdy and I stress the necessity of using the less potent and slower acting sedatives

PRIMARY BRONCHOGENIC CARCINOMA

FROM THE PATHOLOGIC AND RADIOLOGIC
POINTS OF VIEW

WALTER L MATTICK, MD

AND

EUGENE M BURKE BS

BUFFALO

The subject of primary carcinoma of the lungs has attained such widespread interest in the past two decades that it may seem vain repetition to attempt to overcrum an already voluminous literature with further case reports On the other hand, some of the most important therapeutic issues are still unsettled and it is only by evaluating the results of such reports in

increased numbers that final decision on these problems will be possible This paper will attempt only to set forth a few of the highlights as observed in the diagnosis and therapy of this lesion

Since the founding of our clinical unit in 1913, approximately 30,000 patients have presented themselves for examination and 18,000 malignant growths have been discovered Seventy-three cases of car-

cinoma of the bronchus were recognized, an incidence of 1 to 250 At postmortem examination this lesion was noted with half the frequency of carcinoma of the stomach and, like the latter, predominated in males, being five times more frequent in men than in women The greatest prevalence was noted between the ages of 40 and 70 years, the lesion being most commonly observed in the fifth decade

Metastases, as determined by combined clinical and postmortem manifestations, were most numerous in the bones, the incidence was 38 per cent Involvement of distant nodes was slightly less frequent, the incidence being 36 per cent About one third or more of our patients have therefore shown distant metastases at or shortly after the time of diagnosis Extension to the adjoining lobes of the lung or to the contralateral lung or regional nodes occurred with approximately

Fig 1—Adenocarcinomatous type Ia (Figures 1 to 7 inclusive show the histopathologic tendencies of bronchus carcinoma according to classification given in table 2 It should be noted that the fields were representative of the predominant cellular architecture of the particular specimen studied In a few instances however the pleomorphism was so marked as to make such classification impossible)

the same frequency as distant metastases Hence pathologically considered the prognostic outlook, especially as judged from this material, is therapeutically far from promising Table 1 contains a more detailed study of the metastases and extensions and is quite similar to that given for other series with the exception of the low incidence of metastasis to the brain, which may be attributable to our inability to hospitalize the patients and to obtain complete autopsies

On the basis of a common cellular origin from the basal cell epithelial deposits beneath the lowermost layer of the bronchial mucosa, as postulated by Fried,¹ an attempt was made to classify the tumors according to predominating cellular architecture Although universal pleomorphism was generally in evidence, it was usually possible to group the tumors on a histopathologic basis,

From the State Institute for the Study of Malignant Disease Burton T Simpson MD Director
Read before the Section on Radiology at the Eighty-Eighth Annual Session of the American Medical Association Atlantic City N J June 10 1937

they ranged from the most differentiated adenocarcinomatous types, on the one hand through those of squamous cell predominance to those with anaplastic tendencies, on the other. Under such a purely artificial scheme, the greatest incidence was found to occur in

Fig. 2—Adenocarcinomatous type Ib

the squamous cell group where keratinizing tendencies were noted in twenty-two and nonkeratinizing in twelve. The next greatest incidence occurred in the

less differentiated round cell group, in which fourteen tumors were classified. For more complete details reference should be made to table 2.

The histopathologic data as outlined, were further correlated with age, location of the primary lesion, degree of malignancy, radiosensitivity and survival

period without any apparent differences being indicated as might be expected on the theory of common origin of the tumor cells and the universal tendency to pleomorphism.

Two well defined clinical groupings were noted and should be mentioned. The first, based on anatomic location of the primary lesion and previously suggested by Rabin and Neuhof,² divides these lesions into the peripherally located parenchymatous ones and the four to six times more frequent hilus or central types. Only seven cases in our series of seventy-three could be placed in the peripheral classification. This peripheral group is important from the point of view of operability and should be given utmost attention by the roentgenologist, especially in cases in which there are manifestations of isolation of the tumor mass, effusion or chronic abscess formation, the last Edwards³ has shown to be broken down pulmonary cancer in 10 per cent of the cases.

The second interesting variety of cases are those which, for want of a better term, we have designated as the atypical group, with a metastatic history of onset. Here pulmonary symptoms are not manifested, and often roentgen evidence is obscure until some time after the patient has sought relief for distant metastatic phenomena, such as enlarged inguinal glands in one

Fig. 3—Squamous cell type IIa

case, dysphagia in others or tumor of the brain as reported by Fried. Eleven cases in our series, or 15 per cent, were classified in this atypical group. Thus it appears that only by the development of an

³ Edwards, A. T. Malignant Disease of the Lung. J. Thoracic Surg. 4: 107 (Dec.) 1934.

alertness to detect bronchial carcinoma and the use of serial roentgenography in all cases in which the history is suggestive can the clinician or radiologist be led to the early recognition of these lesions

Although the roentgen evidence may not be pathognomonic, because of the ease with which it is obtained, it most often leads to a provisional diagnosis

TABLE 3—Predominating Roentgenographic Characteristics

	Manges and Farrell (70 Cases)	State Institute for the Study of Malignant Disease (38 Cases)
Atelectasis	40%	47%
Increased markings	28%	21%
Tumor mass	24%	1%
Abscess or cavitation	6%	1%
Pleural effusion	2%	15%

of pulmonary cancer. Again the classification of Rabin and Neuhof,² with the usual early finding of atelectasis in the hilus group and demonstration of a tumor mass in the rarer peripheral types, will be helpful from both the diagnostic and the prognostic angles

Fig 4—Squamous cell type IIb

In fact, any unilateral pulmonary involvement in a person past middle age should be viewed with suspicion until proved nonmalignant. Frequent recourse to lateral projections, bronchography with iodized oil and pneumothorax will be found helpful in clearing up the diagnosis in some of the more difficult cases.

The predominating roentgen characteristics were noted in the films available and compared with a similar series studied by Farrell.⁴ The minor variations noted in table 3 tend to indicate that our patients were seen later and showed more advanced lesions than those observed by Farrell.

⁴ Farrell, John T. Jr. Diagnosis of Bronchial Carcinoma. A Clinical and Roentgenologic Study of Fifty Cases. Radiology 26: 261 (March) 1936.

Much controversy has arisen over the proper therapeutic management of bronchial carcinoma. The radiologic literature is full of reported regressions and arrests of pulmonary tumor, but unfortunately most

Fig 5—Squamous cell type III (transitional)

Fig 6—Anaplastic cell type IV (round cell or medullary)

of the studies were uncontrolled by suitable pathologic confirmation and therefore have to be disregarded. An occasional reported arrest of the tumor for three years, with later recurrence and death in five years, as reported

by Gantenberg,⁵ and the noted case of basal cell type of squamous carcinoma of Kahler's,⁶ in which the patient lived nine years after intensive irradiation, should be mentioned. The experience of the Memorial Hospital as recorded by Stewart,⁷ that of the Mayo

Fig 7—Anaplastic cell type V (oat cell)

Clinic, as cited by Vinson⁸ that of Kernan⁹ and our own are all surely far from auspicious in respect to the results of radiation therapy in particular and of all present day therapy in general. A tabulation of the survivals in sixty-four of our cases confirms our opinion.

Most of the therapeutic optimism is at present being displayed by the thoracic surgeon. In two of our cases thoracic surgical procedures were employed with nice palliation in one, in which the involved lobe was removed, and death one month after pneumectomy in the other. Kernan who has had a large metropolitan experience with bronchial carcinoma, stated that he has yet to witness any of the reputed surgical cures. In fact it has been intimated that many reported surgical arrests may, on further histopathologic review, be attributed to the fact

that the tumor was of the not infrequent benign type which is now classified as adenoma.

With the merits of the most approved methods of therapy thus in question it has been our practice to continue protracted intensive irradiation of the majority of these lesions by a four to six field technic with long target distance, supplemented by endo bronchial radon seed implants or, where advisable endothermic coagulation of the endobronchial proliferations. We have often noted marked palliation and occasionally an apparent arrest for periods beyond the average survival for our treated patients, but we have never had a "cure" and are naturally not satisfied with these results. We feel, however, that we must endeavor to improve our irradiation technic, as we have seen few promising surgical prospects in our material and still fewer patients who could or would submit to exploratory and possibly lethal thoracic surgical procedures. It is therefore our opinion, after considering our results and reviewing summarily those of others that the urgent need of today in the management of this lesion is both earlier diagnosis and better therapy, the type of the latter being still undecided.

SUMMARY

In sixty-five of seventy-three cases of bronchial carcinoma from the State Institute for the Study of Malignant Disease the condition was proved by histologic examination of a section obtained at biopsy or autopsy.

Although histologic study in sixty-two cases showed a universal pleomorphism, there was also a predominance of certain histopathologic architectural trends depending on the degree of cellular differentiation.

No correlation between age of occurrence, anatomic location of the primary lesion, radiosensitivity, degree of malignancy, survival and the histopathologic groups could be demonstrated.

The most common roentgen characteristics were atelectasis in the hilus or central type and tumor in the

Fig 8—The three representative clinical types of bronchial carcinoma. A the hilar or central type which is the most common. B the peripheral or parenchymatous type which is less frequent and C an early film of the nonpulmonary type in which the initial complaint is due to metastases often in distant parts.

peripheral type which was found in only 11 per cent of the cases in this series.

The predominance of a central location of the primary lesion, the tendency to early and distant metastases and the marked pleomorphic picture all conspire to make the prognosis unsatisfactory by either surgical intervention or irradiation.

Earlier recognition and better therapy remain the urgent need.

ABSTRACT OF DISCUSSION

DR RALPH E MYERS, Oklahoma City Nearly five years ago I was called in consultation following an incomplete surgical removal of a tumor from the back of a patient about 50 years of age. Examination revealed that this was part of a lung carcinoma which had grown through the chest wall and destroyed about four inches of the fifth rib. In spite of the apparently unfavorable prospects, heavy roentgen therapy was administered. The patient responded amazingly and in about four months had gained over 30 pounds (13.6 Kg). Evidently the irradiation had not been quite intensive enough to destroy the tumor completely. In a few months the symptoms of pain in the region of the growth, of fever and of loss of weight intervened. The skin showed definite changes from the first treatment but after some hesitation it was finally decided that a badly damaged skin with perhaps a living patient was better than a dead patient. About four years ago and about a year after the first series, a second intensive course of roentgen therapy was applied. Today the patient appears perfectly well. He has taken good care of himself and has gone south every winter to avoid the cold. I have been pleased that he has done this as experience leads me to believe that a heavily irradiated lung is often very susceptible to infection. This spring he felt well enough to resume his former occupation. It is evident that this case was a much more favorable one for treatment than it seemed to be in the beginning. Although lung carcinoma is prone to metastasize this one evidently had not done so. Furthermore, its peripheral location permitted cross firing from several portals of entry. Unless something unforeseen intervenes this patient will probably go beyond the five year period. If not, he at least has had wonderful palliation. Surely there are other occasional cases as favorable for treatment as this one. Radiotherapists should therefore undertake the treatment of these patients with the idea that considerable palliation sometimes occurs and that even a cure is possible.

DR EDWARD L JENKINSON Chicago What type was this carcinoma?

DR MYERS It was an undifferentiated type. Its general structure was suggestive of what Dr Geschickter in the *American Journal of Cancer* (December 1934) characterized as adenocolumnar carcinoma of terminal bronchioles.

DR ORVILLE N MELAND Los Angeles I will mention briefly two cases that I had under observation and treatment. A man aged 65, who complained of dyspnea and cough, was treated by Dr Tyler in Omaha by means of x-rays first and then by the implantation of radium element needles through the bronchoscope. He came out to the coast and more needles were inserted in the bronchus. Following this there was complete disappearance of the tumor and disappearance of the atelectasis of the lower lobe. The patient lived for almost five years, he died from metastasis of the liver but there was no evidence of any trouble in the lung itself. A man aged 45 had dyspnea, cough and bloody expectoration and a tumor the size of a baseball in the right upper lobe. It was in such a location that it could not be demonstrated through the bronchoscope. He was given roentgen therapy with complete disappearance of the tumor. It is now five years since he was treated. He is perfectly well and is continuing his work as a clerk in the government service.

DR WALTER L MATTICK, Buffalo Dr Myers and Dr Meland have added a note of encouragement to radiologists. I did not intend to be so pessimistic but I again would emphasize that I am speaking only of pathologically proved cases. We have seen nice palliations in several cases, one patient particularly who was seeded with radon through the bronchoscope went along to termination with beautiful palliation. His doctor, one of the prominent thoracic surgeons, was highly satisfied and wrote a fine letter describing the marked relief this man received. I have not said anything about dosage primarily because I could not go into the question in such a short time. The dose must be the extreme if results are to be expected. I have given doses of as much as 18,000 roentgens in heavily filtered x-rays to these lesions over a period of three months.

AND TWENTY-FOUR CASES

WILLIAM S COLLENS, M.D.

AND

NATHAN D WILENSKI, M.D.

BROOKLYN

In attempting to determine the mechanism responsible for the clinical benefits obtained by constrictive hyperemia,¹ Lewis and Grant² found that during the period of venous congestion produced by the application of a tourniquet there occurred an increase in arterial amplitude in their plethysmographic tracings. More important, however, was their observation that when the constricting band was released there resulted an increase in arterial flow much out of proportion to the original resting period. Thus they called reactive hyperemia. Circulatory arrest created for a period of fifteen minutes would effect an increase in flow of as much as 600 per cent after release.

Barsoum and Smirk³ believe that when tissues are subjected to circulatory arrest they liberate a histamine-like substance which they have been able to demonstrate to be present in increased concentration in venous blood after the release of circulatory arrest. It is thought that this substance accounts at least in part for the creation of reactive hyperemia.

Recognizing that the temporary interruption of the venous return results in increasing arterial amplitude and that the release of the obstruction is followed by a very pronounced form of reactive hyperemia, we decided to apply both these principles in the treatment of peripheral vascular disease. This was done by the construction of an apparatus which automatically produced intermittent periods of venous compression and release of compression. The apparatus was connected to a pneumatic cuff which embraced the proximal portion of the extremity. The cuff was inflated to a pressure necessary to constrict the veins and was then released. This cycle was then continuously repeated so that the final result consisted of alternating periods

of venous congestion (Bier congestive hyperemia) and release of congestion (Lewis reactive hyperemia) We found in our experimental studies that compression of the proximal portion of the extremity up to 80 mm of mercury for alternating periods of two minutes with two minutes of release applied continuously for as much as twelve hours a day had a decided therapeutic effect in

THROMBO-ANGITIS OBLITERANS

Our series contained twenty-seven cases of thrombo angitis obliterans A summary of these cases and results will be seen in table 2 It will be observed that all the twenty-seven patients were suffering from severe rest pain and intermittent claudication There was complete relief of pain in 85 per cent within forty eight hours after the introduction of treatment Of the seventeen cases presenting ulcers twelve healed completely (71 per cent) There was a remarkable

increase in the patients' walking capacity The following are reports of typical cases

CASE 1—N M, a man, aged 40, Jewish, complained for three years of intermittent claudication which became progressively worse, so that at the time of admission to the hospital he was able to walk only one block without claudication He had frequent attacks of migrating phlebitis He also complained of severe rest pain, especially at night He was compelled to cease smoking and had been treated by diathermy, baking massage, hot and cold contrast baths and roentgen therapy of the lumbar spine without relief Examination disclosed evidence of main arterial obstruction in addition to the presence of two phlebotic lesions on the lower third of the right leg No pulsations were obtained in the dorsalis pedis, posterior tibial or popliteal arteries Oscillometric readings and venous filling time before institution of treatment are seen in table 3

The patient was put to bed with a cradle baker over his legs at a temperature of 95 F, and intermittent venous compression was applied to the thigh at 60 mm of pressure for

Fig 2 (case 4)—Arteriosclerotic ulcer of fourteen months duration in a man aged 74 it has a dirty gray base is painful and is becoming progressively larger A before treatment B four weeks after treatment complete healing

two minutes on and off This treatment was maintained continuously for forty-eight hours day and night Following this it was reduced to eight hours a day but the pressure was increased to 90 mm Within twenty four hours all of the rest pain disappeared The phlebotic lesions were gone on the second day The patient was discharged from the hospital on the third day and was subsequently treated as an ambulatory patient receiving two hours of treatment daily There was a very remarkable

increase in his walking capacity from 200 feet to 1500 feet. It will be noted in table 3 that there was an increase in the oscillometric readings and a reduction in the venous filling time indicating a definite increase in the vascular capacity of the extremity. It is also interesting to note that after four weeks of treatment there appeared a growth of hair on the dorsum of the toes, foot and tibial crest.

CASE 2—L. L., a man, aged 29, Jewish, gave a history of an ingrown toenail on the right large toe two years before

Fig 3 (case 5)—A diabetic man aged 59 with osteomyelitis of the fourth toe of five weeks duration presenting secondary infection lymphangitic streaks and edema of the foot and closed major arterial pathways mid thigh amputation had been advised. admission which took one year to heal. For the past year he had complained of intermittent claudication, being unable to walk more than one block. There was an unbearable numbness in the feet, which disappeared on rest. Six months before admission a very painful ulcer developed on the right great toe, which became progressively worse in spite of the therapy he received. He was treated at the Presbyterian Hospital for a short time and subsequently at the Beth Israel Hospital. His

treatment consisted of suction and pressure and daily intravenous injections of hypertonic saline solution during his hospital stay. He had also received diathermy and had stopped smoking and was given bed care. On discharge from these institutions his condition was unchanged. Examination disclosed definite evidence of organic peripheral vascular disease. There were no palpable pulsations in the feet or legs. The oscillometric readings showed a trace at the mid thigh of both the right and the left leg and 0 below the knee at the ankle and at the dorsalis pedis artery of both legs. The venous filling time was 50 seconds in the right and 30 seconds in the left foot.

There was a cyanotic rubor of the right foot in the dependent position and it was colder than the left. An unhealthy ulcer one-half inch in diameter and very tender to touch was present, with surrounding edema. In view of his age and the absence of calcification of vessels in the x-ray films a diagnosis of thromboangitis obliterans with a gangrenous ulcer of the right great toe was made. He came to the hospital in great pain and was consuming large quantities of codeine and salicylates to get some relief. The patient was given continuous intermittent venous occlusion at 30 mm of pressure. There was a remarkable relief of pain within twenty-four hours and at the end of

two days islands of healthy granulation tissue began to appear in the base of the ulcer. One week after admission the entire base was covered with healthy granulations. At the end of four weeks the patient walked out of the hospital with complete epithelization of the ulcer and free from pain. Figure 1 shows the ulcer before and after treatment.

ARTERIOSCLEROSIS OBLITERANS (NONDIABETIC)

We collected thirty-three cases in this series in which twenty-eight patients were males and five were females. It will be noted from table 4 that complete relief of pain within forty-eight hours was obtained in 82 per cent of the cases. Four patients who came to us with chronic indolent ulcers were entirely healed.

CASE 3—J. H., a man, aged 66, Jewish, gave a history of intermittent claudication of ten years' duration. The symptoms had been getting progressively worse and the distance that he had been able to walk before cramps developed in the legs was getting shorter. Within the last two years he had begun to complain of a considerable degree of rest pain keeping him awake at night and necessitating the use of large doses of narcotics. His previous treatments had consisted of baking, rest, contrast baths and diathermy. Physical examination was

Fig 4 (case 6)—Diabetic gangrene in a woman aged 58 with closed major vessels gangrene and osteomyelitis of the third toe edema of the foot lymphangitis and fever. A before treatment B spontaneous expulsion of sequestrum. Note exuberant granulation tissue two weeks after treatment C four weeks later completely healed.

negative except for the condition in the lower extremities. The feet were cold, the skin was dry and no pulsations were obtained in all the major vessels. The venous filling time was thirteen seconds in the right and fifteen seconds in the left foot. At the rate of 11 paces every five seconds he was unable to walk more than 350 feet before claudication developed. In view of his age the diagnosis of peripheral vascular sclerosis was made. He was not diabetic. He was given intermittent venous compression at 80 mm for two weeks. All the rest pain was completely relieved within twenty-four hours. Oscillometric readings were improved.

Case 4 illustrates our experience with a case of peripheral vascular sclerosis with a chronic indolent ulcer on the right great toe of fourteen months' duration.

CASE 4—A man aged 74, Jewish, bedridden, complained of severe rest pain and inability to walk. He had been unsuccessfully treated with various ointments, wet dressings, baths, baking and diathermy. On admission he presented all the signs of chronic obliterative arterial disease with marked obstruction of the sclerotic type. His feet were cold, there were no pulsations, and oscillometry showed no readings below the knees. There was a dirty gray infected ulcer on the medial surface of the right great toe with surrounding edema, redness and marked tenderness (fig 2 A). X-ray examination showed calcification of the major vessels. Intermittent venous occlusion was applied continuously at 50 mm. In twenty-four hours the pain was entirely gone. On the fourth day islands of healthy granulation tissue began to appear. In four weeks the ulcer was completely healed (fig 2 B).

ARTERIOSCLEROSIS OBLITERANS (DIABETIC)

There are forty-eight cases in this group in which twenty-two patients were males and twenty-six females. Seventy-one per cent of the entire group had open lesions. It will be noted in table 6 that 60 per cent

Fig 5—Case of thrombo-angitis obliterans of fourteen years duration closed major vessels ulcer of seven years duration no healing treated continuously by Dr. Samuels for seven years three times a week with hypertonic saline solution intravenously. A before treatment B five weeks after treatment complete healing.

were completely relieved of pain in forty-eight hours and 33 per cent were partially relieved. There occurred complete healing of lesions in 76 per cent of our cases and 24 per cent came to amputation.

The following cases are examples of our experience in this group.

CASE 5—M. A. a man aged 59, Jewish, had had a relatively mild degree of diabetes for ten years. He had been suffering from an infected right fourth toe which became progressively worse for five weeks before admission. Pain was very severe and kept him awake at night. During his stay in another hospital mid thigh amputation was advised because of the spreading lymphangitis and fever associated with progressive gangrene. On admission he showed the presence of an area of gangrene involving the middle portion of the dorsum of the right fourth toe. This gangrenous patch was firmly adherent to the deeper structures. The toe was red and swollen (fig 3 A). There was edema on the dorsum of the foot and lymphangitic streaks were present. X-ray examination disclosed the existence of osteomyelitis of the middle phalanx and calcification of the major vessels. No pulsations were obtained. Oscillometric readings were absent in both legs below the knees. There was a marked delay in the venous filling time. The diagnosis was diabetes arteriosclerosis obliterans and osteomyelitis with gangrene of

the fourth right toe. The patient was given intermittent venous occlusion at 50 mm of mercury and the relief of pain was almost immediate, occurring within eight hours.

This treatment was given for twelve hours daily. At the end of two weeks islands of granulation tissue and bleeding points began to appear in the margins of the gangrenous slough.

At the end of four weeks there occurred a spontaneous extrusion of the sequestrum, which was easily picked out with a pair of forceps. Following that the base of the ulcer showed a progressive growth of healthy granulation tissue. In twelve weeks the patient was discharged with the toe completely healed (fig 3 B).

CASE 6—M. G., a woman, aged 58, Jewish, had been diabetic for twelve years. She also had hypertension (220 systolic 110 diastolic) and peripheral vascular sclerosis. She had been receiving a high carbohydrate diet with 15 units of insulin once a day for one year. Two weeks before admission because of marked rest pain and coldness in the feet associated with peripheral vascular sclerosis she had applied a thermalite biker to the feet and sustained a burn with bleb formation on the dorsum of the middle toe of the right foot. This burn became infected, tissues broke down and when she appeared for examination there existed a gangrenous lesion with ulceration covering the entire dorsum of the third toe (fig 4 A). The surrounding region was red and edematous. The temperature was 101 F. Oscillometric readings showed 0 above the ankle and one fourth below the knee. No palpable pulsations were obtained in the leg. The venous filling time was thirty-two seconds. The X-ray films showed osteomyelitis involving the middle phalanx of the third toe. The carbohydrate tolerance was broken obviously the result of the infection. The patient was put to bed, a warm boric acid dressing was applied to the foot, a cradle biker was put in place to maintain the environmental temperature at 95 F., and intermittent venous compression

TABLE 7—Summary of Cases of Embolus and Acute Arterial Thrombosis

no amputation	

was given at 40 mm alternating two minute cycle continuously. The patient experienced a very prompt relief of pain. In three days there was extensive bleeding from the lesion. After ten days of treatment the sequestrum was expelled. This was most unusual about this case was the appearance of exuberant granulation tissue (fig 4 B). This was the first time that we had seen the appearance of exuberant granulations in a lesion on an extremity which had an interference in circulation from obliterative arterial disease. It was so pronounced that we found it necessary on three occasions to apply a silver nitrate stick, a procedure which we otherwise would have carried out with great trepidation under conditions associated with

peripheral vascular obstruction. Four weeks after admission the patient was discharged with epithelization and complete healing of the lesion (fig 4C).

We have included in our series seven cases comprising a group in which there were acute embolic phenomena to the major vessels of the lower extremity or thrombosis. One patient suffering from subacute bacterial endocarditis had an embolus to the right popliteal artery. Two patients with auricular fibrillation had emboli in the femoral artery and four patients with peripheral vascular sclerosis had attacks of acute popliteal thrombosis. In all the cases a remarkable relief from pain was noted within eight hours. Three patients completely escaped gangrenous destruction. One patient in whom a patch of gangrene had developed on the great toe recovered completely. In the patient with subacute bacterial endocarditis a small patch developed on three toes, but she died three weeks later from a cerebral embolus. One patient with auricular fibrillation in whom gangrene of the foot developed was a poor operative risk and died of congestive heart failure. The seventh had a mid thigh amputation and died two days after operation (table 7).

There are also included seven cases of large chronic varicose ulcers of long standing, all of which healed completely. The details of these cases will be presented in a separate communication.

COMMENT

An important problem which always arises in a clinical investigation is concerned with establishing adequate control conditions. It is very obvious in a group such as this that bed rest, the continuous maintenance of an environmental temperature at 95 F and the elimination of tobacco would in themselves play a part in producing beneficial effects. We must state, however, that most of our patients had already experienced this form of control before coming under our care and that the only variable which we created was that of introducing a state of intermittent venous compression.

An examination of our tables of peripheral vascular sclerosis discloses some rather interesting information. It will be noted that there was a somewhat larger incidence of arteriosclerosis obliterans in diabetic than in nondiabetic patients. Yet there occurred a remarkable difference in sex distribution. While among the nondiabetic patients 85 per cent were males, in the diabetic group only 46 per cent were males. This is easily understandable when one realizes that diabetes occurring in later life is predominantly in females. Another important phase of this subject deals with the incidence of ulcer and gangrene. While 24 per cent of the nondiabetic group presented open lesions, 71 per cent of the diabetic group was similarly affected. This simply means that, although sclerotic changes in peripheral blood vessels occur in the nondiabetic almost as frequently as in the diabetic, the vulnerability of diabetic tissues to infection results in thrombotic processes that subsequently terminate in death of tissues.

It is very obvious that no procedure can change the structural characteristic of an organically altered major blood vessel. We do not believe that an artery obliterated by sclerotic degenerative changes can be made subsequently to permit the transport of blood. Any attempt at improving the vascular capacity of an extremity whose major vessels had been obliterated by degenerative changes can be effected only through the development of a collateral circulation or through the release of a spastic phase of a partially obliterated

artery already organically altered. This we believe can be accomplished by very powerful and active local vasodilatation. Lewis and Grant in their studies thought that the active vasodilatation which followed the discontinuance of temporarily interrupted circulation was the result of the release from tissue cells of an H substance which possessed strong vasodilator effects. We have found in our own plethysmographic studies of patients suffering from thrombo-angitis obliterans or sclerotic obliterative arterial disease that at the height of venous congestion and during the state of reactive hyperemia the arterial amplitude increased to such a remarkable extent that diastolic pressure in the pulse could occasionally be observed.

In analyzing the beneficial effects of alternating suction and pressure we are of the impression that the phase of suction which builds up a negative pressure far greater than intravenous pressure results in venous congestion. Any one looking through the transparent cellulose acetate boot at the extremity during the phase of suction will see the enormous distention of the superficial veins with a cyanotic flush of the extremity, which is obviously venous congestion. We do not see any benefits that can be derived from the pressure phase of suction and pressure. We can, however, understand that the pressure phase can have deleterious effects for two reasons, first, it encourages the active introduction of infected thrombotic material from the margins of ulcers and gangrene, second it retards the development of reactive hyperemia which must follow the phase of suction. This may explain the reason for the numerous accidents that occur following the use of suction and pressure and also the reason for the great many contraindications that have been built up by men working with it. If that is the mechanism responsible for the beneficial effects derived from our method as well as the suction phase of suction and pressure, we feel that our procedure is capable of producing a more profound therapeutic effect because of the ability to apply venous compression for longer periods than suction. Lewis and Grant definitely demonstrated that the longer the venous congestion was applied and the greater the degree of pressure up to 90 mm of mercury, the more profound was the reactive hyperemia.

Lewis and Grant made a significant observation when they noted a direct relationship between the degree of reactive hyperemia and the environmental temperature of the extremity. They found when they maintained venous compression at the same level and for the same periods but altered the environmental temperature that the higher the temperature the more pronounced was the reactive hyperemia. On the basis of this observation we have recently modified our technic in the treatment of the ambulatory case and taken advantage of this important observation. When the patients come for daily treatments a short wave or diathermy apparatus is used with a flat plate electrode applied to the plantar surface of the foot and a cuff electrode placed below the knee. The pneumatic cuff for producing intermittent venous compression is at the same time applied at the mid thigh and the two treatments are given simultaneously for approximately one hour. We have been significantly impressed with the marked clinical benefits that are obtained when the phenomenon of reactive hyperemia is thus accentuated by elevating the temperatures of the deeper structures. The surface temperature of the leg need not be elevated higher than 100 F.

It will be noted from our tables that we had a certain percentage of failures, especially pronounced in the diabetic patients suffering from peripheral vascular sclerosis and gangrene. In our series of thirty-four cases of diabetic ulcer or gangrene, 24 per cent came to amputation. That figure is vastly lower than commonly quoted figures of 50 per cent under the influence of all other methods of treatment. We do not claim that this is a cure-all for every case of obliterative vascular disease, but one must recognize the limitations of any method when one is contending with a case which presents such profound vascular obliteration that the potential collateral flow becomes involved. Under such circumstances a certain percentage of these cases must eventually come to amputation. It then becomes a question of lowering that figure by methods which are capable of favorably influencing extremities that have the capacity to improve collateral arterial flow.

We feel that our method is capable of increasing vascular capacity, as is evidenced by the following phenomena: relief of rest pain, increase of walking capacity, regeneration of tissues, improvement in the nutrition of nails, and the growth of hair over areas which had become denuded as the result of obliterative arterial disease. We were able to note in one case the development of granulation tissue to such a degree of exuberance that it necessitated the use of silver nitrate on three different occasions in order to prevent the development of keloid.

STUDIES OF THE BLOOD CHEMISTRY IN THYROID CRISIS

WALTER G. MADDOCK, M.D.

SVEND PEDERSEN, Ph.D.

AND

FREDERICK A. COLLIER, M.D.

ANN ARBOR, MICH.

In reviews of the cause of death from goiter, thyroid crisis generally accounts for more than half of the mortality.¹ At the University Hospital from 1925 through 1933, 70 per cent, or eighty-eight, of the 123 deaths from goiter were due to this cause. Fifty-one of these eighty-eight occurred in the medical service,² before the patient could be improved to a point at which an operation might be considered, and thirty-seven occurred postoperatively.³ The same greater frequency of preoperative deaths from crisis was reported by Lahey⁴ in 1928.

Our interest in thyroid crisis was aroused because of the apparent futility of treatment once this complication becomes well established. This particular ineffectiveness has been recognized for years, and emphasis has properly been placed on elimination of the factors known to precipitate a crisis and on the adequate use of measures to ward off or lessen an

impending crisis,⁴ whether it is before or after the operation. As a result of constant vigilance, the reaction of the majority of patients operated on for hyperthyroidism is now mild. In a few instances the fever, tachycardia, sweating and restlessness are a little greater than desired, but usually these signs subside in from twenty-four to forty-eight hours. Fortunately a reaction severe enough to be called a thyroid crisis is encountered only at rare intervals.

As one observes a patient in a thyroid crisis the impression is that profound toxemia is present. Metabolic processes appear to be so tremendously disturbed that some alteration in body chemistry producing the effect ought to be discoverable and ought to be measurable if only one knew what to measure. In the hope of finding significant data in this regard we made a number of preoperative and postoperative studies of the blood chemistry on patients with hyperthyroidism during the past two years.⁵ The investigating staff was constantly on the alert to apply the studies to patients with severe reactions, and a few patients in typical thyroid crisis were available.

CHIEF ELECTROLYTES OF THE BLOOD

It is reasonable to believe that if any serious disturbance of the electrolytes were present in the blood of patients with hyperthyroidism the abnormality would have been found previously, since extensive general studies have been made. A few suggestions for possible investigation, however, were found.

Sodium—Schneider⁶ has reported extreme depletions of the serum sodium content in hyperthyroidism, one patient having only 53 mg per hundred cubic centimeters, which is about 16 per cent of the normal. We found essentially normal values for serum sodium for ten patients with hyperthyroidism, two of whom died preoperatively and one postoperatively of thyroid crisis.⁷ This lead was not helpful to us or to Feldmaus⁸ and Pemberton.¹

Potassium—A study of this ion in relation to thyroid crisis was suggested for three reasons: (1) the fact that potassium is a toxic substance,⁹ (2) the statement that all the effects of epinephrine—a substance possibly concerned with thyroid crisis—can be produced by potassium¹⁰ and (3) the fact that the serum potassium content is found to be increased immediately after injections of epinephrine.¹¹ Determinations of the serum potassium were made on fifteen patients with hyperthyroidism, and the values obtained were all essentially normal, even the value for a specimen taken postoperatively two hours before death from a patient with a temperature of 105 F. Pemberton¹ found a normal serum potassium content in two patients dying from severe postoperative hyperthyroid reactions. Serum potassium values much higher than any we

found have been observed in patients with other conditions¹² showing no evidence of toxicity

Calcium and Phosphates—More than forty years ago it was pointed out that disorders of the bony skeleton appeared to be associated with hyperthyroidism. That the administration of thyroid gland to rabbits markedly increases the urinary output of calcium was definitely shown by Parhon,¹³ and Aub and his associates¹⁴ furnished conclusive proof of an

hepatic function tests dealing with the disturbance of carbohydrate metabolism, Kugelmann²⁰ concluded that not only does the liver of the hyperthyroid subject show a failure to store glycogen but it is unable to convert large amounts of levulose to dextrose, a process easily accomplished by the normal liver

With this evidence of disturbed hepatic function and severe hepatic disease at hand, our point of interest was whether or not the postoperative reaction of the patients was due to hepatic damage. The pathologic process in the liver was certainly extensive, and of possible significance is the fact that hyperthermia accompanies other so-called liver deaths.²¹

From the considerable number of tests available²² for estimations of hepatic function three measurements were chosen: (1) the blood bilirubin contents, (2) the excretion of bromsulphalein dye and (3) the amino acid nitrogen content of the blood. This selection was made for the following reasons:

The finding of abnormal amounts of bilirubin in the blood stream reflects the bilirubin excretory function of the liver unless excessive amounts of bilirubin are being formed as a result of increased hemolysis of erythrocytes. If this condition has not occurred and there is no obstruction to the excretory ducts of the liver, the finding of hyperbilirubinemia indicates impairment of function of the liver parenchyma. Studies have shown that such impairment must be moderately advanced and generalized before abnormal values for blood bilirubin, above 3 mg per liter, are obtained. From the extent of the hepatic lesions observed at autopsy on patients who died of hyperthyroidism, abnormal results from this test were expected.

Among the various dye excretion tests, that in which bromsulphalein is used and 5 mg per kilogram of body weight²³ administered was most desirable. As for the

Chart 1 (case 1)—Mild postoperative course in spite of considerable evidence of impaired hepatic function

increased excretion of calcium and inorganic phosphate by human beings with hyperthyroidism. In spite of this marked abnormality Aub¹⁴ found normal values for these constituents in the serum. Similar normal values were found for the patients of this study.

In summary, our search for abnormalities of inorganic ion concentrations in the blood of patients with hyperthyroidism has not been fruitful.

HEPATIC FUNCTION IN HYPERTHYROIDISM

From various sources evidence has accumulated to show that damage to the liver occurs in hyperthyroidism. Clinical reports of jaundice¹⁵ are not infrequent, and the diagnosis of acute yellow atrophy¹⁶ has been made on a few occasions. In a study of the hepatic pathology, Weller¹⁷ observed well marked chronic parenchymatous hepatitis at autopsy in twenty-two of forty-four selected cases of exophthalmic goiter, while but one example of the same degree of change was found in a control series of the same number of autopsies. Beaver and Pemberton¹⁸ similarly found a high incidence of degenerative changes in the liver of patients dying of hyperthyroidism. Studies of the hepatic function are in accord with these data, Youmans and Warfield¹⁹ having shown impairment in the excretion of phenoltetrachlorophthalein dye in 50 per cent of forty-four patients studied. From a review of

Chart 2 (case 2)—Severe postoperative thyroid crisis with only moderate evidence of impaired hepatic function

determination of bilirubin rather widespread and extensive hepatic disease is necessary to cause an abnormal result, which is more than 10 per cent retention of the dye at the end of one-half hour. An advantage of this test for a continued study, such as ours, was

brought out by Soffer,²² who stated that, although there is apparently only a rough quantitative relationship between the degree of retention of the injected dye and the hepatic damage in any patient who is observed over an extended period with this test, the results will indicate whether the hepatic lesion is becoming more extensive or is regressing.

The determinations of the amino acid nitrogen in the blood²⁴ were a search for evidence of profound hepatic damage. The deamination of amino acids in man occurs mainly in the liver, and this function is lost only in the terminal stage of acute yellow atrophy.²⁵ For the patients with hyperthyroidism essentially normal values were found, and the data obtained will be shown in only two cases (charts 1 and 2).

mal and the retention of dye being practically complete in the majority of cases. Using the hippuric acid test on a group of patients with hyperthyroidism, Lahey and Bartels²⁶ found increased impairment of the hepatic function on the sixth postoperative day. Patients operated on for other diseases have not regularly shown the same disturbance of hepatic function.²⁷ This evidence of hepatic dysfunction on the day after the operation is in accord with the observation of a high percentage of acute degenerative changes in the liver of patients who have died of hyperthyroidism, many in the immediate postoperative period.

4 On succeeding days the hepatic function of the patients improved a variable time being necessary before it returned to the preoperative level.

Evidence of Impaired Hepatic Function in Patients with Hyperthyroidism from Data on the Blood Bilirubin and the Bromsulfalein Excretion

* Retention of 100 per cent or more of the dye is considered to be total. The apparent paradox of more than 100 per cent retention is due to the fact that the colorimeter standards developed originally for the administration of 2 mg of the dye per kilogram of body weight have been retained although a 5 mg dose is used. Differentiation of color with higher standards was found to be difficult.

In the accompanying table are presented the values for blood bilirubin and the data on bromsulfalein for the seventeen patients studied. The following points were significant:

1 Eight, or 61 per cent, of the thirteen patients with toxic goiter showed evidence of impaired hepatic function preoperatively, by having a blood bilirubin content above 3 mg per liter, a retention of bromsulfalein dye of more than 10 per cent or both.

2 A relationship between the severity of the hyperthyroidism and the hepatic damage was shown, first, by the finding of normal hepatic function in four patients with nontoxic thyroids studied as a control group and, secondly, by the finding of an average basal metabolic rate of only +33 per cent for the five toxic patients with normal hepatic function, in contrast to an average of +54 per cent for the eight toxic patients with evidence of hepatic damage. The same direct relationship between the extent of the pathologic process in the liver and the severity of the disease was found by Beaver and Pemberton¹⁰ in a correlation of clinical and postmortem data.

3 The operation produced a marked effect. On the first postoperative day the data whether normal before or not, showed a striking impairment of hepatic function, the blood bilirubin content being above nor-

mal and the retention of dye being practically complete in the majority of cases. Three cases in particular emphasized this.

CASE 1—*Considerable evidence of hepatic damage and mild postoperative reaction.* E H, a woman, aged 46, on admission to the hospital had a history of goiter of thirty years' duration, symptoms of severe thyrotoxicosis for two years and intermittent jaundice for the past six months. No cause for the jaundice except toxic hepatitis could be found. The course in the medical service was unsatisfactory, the basal metabolic rate increased from +36 per cent to +60 per cent, the jaundice increased and a continued loss of weight and diarrhea occurred. Operative treatment was decided on, and a right hemithyroidectomy was done. Postoperatively the patient's general condition was good in spite of a marked rapid increase in the yellowness of the skin to a canary color. The clinical observations, showing a comparatively mild postoperative reaction, and the data on hepatic function, with, most significantly, the blood bilirubin up to 240 mg per liter on the third postoperative day, are given in chart 1. At an examination three months later the blood bilirubin content was normal.

CASES 2 and 3—*Only moderate evidence of hepatic damage and severe thyroid crisis postoperatively.*

In D H, a girl aged 17, goiter developed three years previous to admission. All the symptoms and signs of exophthalmic goiter were present. The initial metabolic rate was +70 per cent and the subsequent improvement was

irregular and slow. Severe thyroid crisis developed about eight hours after a right hemithyroidectomy was done and continued for three days. The clinical observations and the data on the blood chemistry are shown in chart 2. The blood bilirubin content and the retention of bromsulfalein during the time of the crisis were not nearly as high as the values found for several other patients with comparatively normal postoperative courses. Throughout the height of the reaction the amino acid nitrogen content of the blood, which is increased in profound hepatic damage, was unchanged. The occurrence of acute pulmonary edema during the crisis and the epinephrine study will be discussed later.

V B, a woman, aged 36, was admitted to the medical service in a condition of thyroid crisis. The first metabolic rate obtained was +75 per cent. With careful treatment her response was considered to be satisfactory enough to allow multiple stage operations. Approximately thirty hours after a hemithyroidectomy a typical crisis developed, and she died twelve hours later. Evidence of hepatic damage twenty hours before death was only moderate. The amino acid nitrogen content of the blood was entirely normal. This patient also had acute pulmonary edema during the thyroid crisis.

In summary, two conclusions from the studies on hepatic function were of particular interest. First, the data on preoperative hepatic function gave no indication as to the mildness or severity of the postoperative course. Second, in the postoperative period an increase in the incidence and the degree of impaired hepatic function and an increase in hyperthyroid reactions were found, but there was no evidence to show that one was the cause of the other. A third factor could be responsible for both.

EPINEPHRINE

In this country the relationship between the nervous system, the adrenals and the thyroid gland has repeatedly been emphasized. Crile²⁸ has on many occasions pointed out the interdependence of these structures and bases his treatment of hyperthyroidism on the concept that it is a disorder of the entire kinetic system. In a recent article on postoperative hyperthyroid reactions, Pemberton¹ presented the following two theories as to cause: (1) sudden increase in amount of thyroid secretion (either normal or abnormal) and (2) hypersecretion of epinephrine. In the discussion of these theories the evidence was much stronger for the latter. In 1914 Cannon²⁹ showed that pain and strong emotional factors stimulate the suprarenal medulla to greater activity. With Cattell³⁰ he showed that injections of epinephrine induce secretory activity of the thyroid gland. Levy³¹ added the fact that thyroid secretion sensitizes the sympathetic system to epinephrine. Guided by Levy's work, in 1918 Goetsch³² brought out a test for early hyperthyroidism, the significant finding being an increased response to injected epinephrine. Of particular significance in regard to the theory that excessive secretion of epinephrine causes thyroid crisis was the observation of Goetsch and Ritzmann³³ that the operative reaction is identical in nature with the preoperative responses of the same patient to a subcutaneous injection of epinephrine, the variation being only in degree.

From this discussion it is evident that a measurement of the epinephrine content of the blood of patients with hyperthyroidism would be of value. Such measurements were done in the early part of this century, and although the methods employed have been criticized the results are worthy of mention. Fraenkel³⁴ in 1909, using a rabbit uterus procedure, reported the finding of increased amounts of epinephrine in the blood of three patients who had exophthalmic goiter. Broking and Trendelenburg³⁵ in 1911, using a method dependent on the perfusion of the vascular system of frogs, reported increased epinephrine in four out of five cases studied.

In January 1936 we began to use the method developed by Whitehorn³⁶ for the estimation of epinephrine in venous blood. Two chemical principles are involved: (1) the use of silicic acid for the separation of epinephrine from other substances which might interfere with the test and (2) the reduction of arsenomolybdic acid by epinephrine, the resultant blue solution being read colorimetrically. The sensitivity of this test is indicated by Whitehorn's experiments, in which an average of 92 per cent of epinephrine added to blood was recovered and epinephrine detected when its concentration reached or exceeded 1 part in 50,000,000. This amount is believed to be about twenty times greater than the concentration in normal venous blood.³⁷

The test was performed on sixteen patients with hyperthyroidism, both before and after the operation. The result was negative in five and positive in eleven. In four of the latter thyroid crisis developed, two died preoperatively and one postoperatively. The most positive value obtained was for patient D H (chart 2), who had the most severe thyroid crisis seen during the past two years. The reaction became negative shortly after the crisis subsided.

In a consideration of these data there was much to be desired. The Whitehorn test, in the first place, is still an unproved method when one is dealing with disease conditions, and, secondly, it has never been checked against methods of biologic assay. In addition, the methods of biologic assay advocated at this time have not been used on patients showing severe postoperative hyperthyroid reactions. It seemed logical to carry out such studies.

Of the procedures for biologic assay available, the combination used by Stewart³⁸ and Rogoff³⁷ appeared to be most desirable.³⁹ This consists of an inhibition of the contractions of a rabbit intestinal strip and an augmentation of the contractions of the rabbit uterus. As far as is known, only epinephrine will produce these two effects, and the reaction is roughly quantitative.

In four patients with hyperthyroidism the Whitehorn test and the biologic assay⁴⁰ were employed. The following case was chosen for consideration.

CASE 4—J S, a man, aged 27, had the symptoms and signs of severe exophthalmic goiter six months prior to admission. The loss of weight was 40 pounds (18 Kg). An early basal

40 Dr Carl Moyer performed the biologic assay determination.

metabolic rate was reported as + 105 per cent. The response to preparatory treatment was good, but multiple stage operations were considered advisable. A right hemithyroidectomy was done on May 25. Chart 3 shows the postoperative reactions of temperature and pulse and the results of the epinephrine determinations.

As can be seen in chart 3, the Whitehorn test, which was positive both preoperatively and on the first postoperative day, was negative on the third postoperative day. With the rabbit intestinal segment an epinephrine-like reaction was obtained preoperatively and on three occasions postoperatively. It was of interest that the peak of the postoperative hyperthyroid reaction was coincident with the greatest value obtained by biologic assay. The reaction of the intestinal segment obtained at this time, the first postoperative day, was similar to the effect of 1 part in 30,000,000 of epinephrine. This concentration is from ten to thirty times the normal and corresponds to such concentrations in systemic blood as might be obtained if all the epinephrine liberated from the adrenal glands by powerful stimulation of the

Chart 3 (case 4)—Data from tests for epinephrine in the peripheral venous blood of a patient with hyperthyroidism with special reference to the postoperative hyperthyroid reaction.

splanchnic nerves remained in the circulation.⁴¹ The results in the other three cases were essentially the same as in this one.

In relation to the possibility of increased amounts of epinephrine in the blood, two other observations on patients with postoperative hyperthyroid reactions are worthy of further thought.

1 Pulmonary Edema—During three typical examples of severe postoperative thyroid crisis observed during the past two years the raising of large amounts of frothy, slightly blood-tinged sputum was an alarming finding. Two of the patients died, and at the autopsy on one patient marked edema of the lungs, with confluent, acute, fibrinopurulent, lobular pneumonia was observed. A diffuse pneumonic process of varying degrees is mentioned among the postoperative complications by most authors, but pulmonary edema has received little attention. Patient D. H. (chart 2), the third patient in whom pulmonary edema was noted, recovered from this complication rather suddenly on the afternoon of the third day of her crisis (February 9) and was out of the crisis on the following morning. At this time (February 10) the chemical test for epinephrine, which previously had been positive, was found to be negative.

As mentioned before, Goetsch³³ has shown that all the common operative reactions in the patient with hyperthyroidism can be brought out by the administration of epinephrine hydrochloride to the same patient prior to the operation. Can excessive amounts of epinephrine be responsible for the pulmonary edema observed by us? The literature furnished significant data in this regard.

In 1902 Bouchard and Claude⁴² observed pulmonary edema and death in the normal rabbit after the intravenous injection of epinephrine. Auer and Gates⁴³ have published some exceptionally fine colored plates showing this phenomenon; they demonstrated that when the vagi are divided smaller doses of epinephrine are effective in producing the edema and that atropine then exerts a protective action. In the clinical literature, reports⁴⁴ were found of pulmonary edema occurring in the presence of chromaffin cell tumors, which are known to secrete epinephrine. Also, a fatality has been reported⁴⁵ due to the accidental administration of 75 cc of 1 to 1,000 epinephrine solution subcutaneously, death occurring four hours after the onset of acute pulmonary edema. This is a tremendous dose, but experimentally in rabbits it has been shown⁴⁶ that when administered subcutaneously large doses are necessary to produce this effect.

From references cited there is evidence for the belief that pulmonary edema seen in instances of thyroid crisis can be the result of increased amounts of circulating epinephrine. We consider that in the past we have overlooked this respiratory complication, in many instances attributing the cyanosis and the excessive mucus to bronchopneumonia and tracheitis.

2 Epinephrine Disturbing Liver Function—At this point it seemed logical to inquire whether the disturbance in hepatic function and the pathologic changes in the liver of patients with hyperthyroidism could be due to epinephrine. Besides the production of pulmonary edema already mentioned, early work with adrenal extract showed that it disturbed the carbohydrate metabolism of the liver⁴⁷ and that the liver was intimately concerned with destruction of epinephrine.⁴⁸ In 1934 Perazzo⁴⁹ demonstrated in dogs that moderate doses of epinephrine injected intravenously produce well advanced fatty degenerative changes. This pathologic process is essentially the major acute lesion observed by Weller¹ and Beaver and Pemberton¹⁸ in the liver of patients who died of hyperthyroidism.

COMMENT

From the several studies discussed in this paper, two observations merit comment.

1 Impairment of hepatic function was not found to be the cause of postoperative hyperthyroid reactions, but its presence to a considerable degree in the immediate

postoperative period was definitely shown. Since the protective action of carbohydrates on the liver has been definitely established, the occurrence of impaired hepatic function in the immediate postoperative period of patients operated on for hyperthyroidism is an excellent reason for the administration of dextrose solutions at this time. For most surgeons³⁰ this treatment is a matter of routine in the care of such patients, and from experience its value has been proved.

2. Concerning this preliminary report on the finding in the blood of patients with hyperthyroidism of increased amounts of a substance which yields biologic reactions similar to those of epinephrine, no positive identification of this substance as epinephrine can be made at this time. Confirmatory tests are now being carried out.

The occurrence of thyroid crisis has been definitely decreased by better preparation of the patients, by selective operative procedures and by adequate postoperative care. With further knowledge of the cause of thyroid crisis, specific measures may be possible to avoid this serious complication.

1313 East Ann Street

ABSTRACT OF DISCUSSION

DR GEORGE CRILE JR., Cleveland. The development of the Whitehorn test for epinephrine opens a wide field for research. It will be interesting to see whether a positive test for epinephrine is a finding specific for patients in thyroid crisis. It is possible that the terminal phase of any condition associated with circulatory failure, pulmonary edema or anoxemia may call forth an emergency output of epinephrine. If this should prove to be the case, a positive epinephrine test might indicate the presence of severe anoxemia rather than a specific thyroid-adrenal relationship. Dr Crile Sr, Dr Dismore and I have recently studied 200 cases of hyperthyroidism. In this group there were four instances of liver failure. The onset of symptoms was usually on the third postoperative day, always well after the peak of the postoperative pulse and temperature reaction. The first indication of hepatic insufficiency was confusion or delirium, accompanied by an elevation of the icterus index to as high as 75, the average being 42. Three of the four patients who presented clinical evidence of liver failure were over 60 years of age, an observation that is consistent with Beaver and Pemberton's autopsy results. In their series, atrophy and cirrhosis of the liver was more marked in elderly patients with hyperthyroidism than in patients in the younger age groups. The figures of Dr Maddock and his co-workers also show a correlation between the diminution of liver function and the age of the patients. Thus the degree of hepatic impairment would appear to be related to the age of the patient as well as to the severity of the hyperthyroidism. I agree that a solution of dextrose given by the continuous intravenous drip method is of great value not only in the prevention and control of thyroid crisis but also in combating liver failure. But 5 liters of 5 per cent dextrose solution contains only 1,000 calories, and the caloric intake necessary to maintain weight in a patient with a basal metabolic rate of plus 100 per cent may be as high as 5,000 calories a day. When after operation such a patient stops eating, it is vital to restore the metabolic equilibrium by restoring the intake of food. If food is refused, forced feedings can be given through a nasal tube. I have seen delirium which did not respond to any other method of treatment clear up rapidly following restoration of caloric intake by high carbohydrate feedings given through a nasal tube.

DR JOHN PAUL NORTH, Philadelphia. The authors have made a distinct contribution in demonstrating an increase of

epinephrine in the blood in hyperthyroidism and this is further evidence of the close relationship between the thyroid and adrenal glands. The proof that this increased epinephrine is the cause of thyroid crisis requires more evidence than has been presented. The case in favor of epinephrine rests on laboratory tests the interpretation of which is no more certain than that of the liver function tests. These admittedly are not very satisfactory. The Whitehorn test has not been subjected to extensive clinical trial. Its originator confesses inherent difficulties which limit the accuracy of the method to dilutions in excess of one part of epinephrine in 50 million, yet in one of the cases just reported a positive Whitehorn test is recorded in which the corresponding biologic assay showed a dilution of one in 120 million. Obviously the concentrations of epinephrine encountered in human venous blood approach the range of probable error of the method itself. It is well known that anoxemia stimulates the production of epinephrine. Thus, if nitrous oxide or avertin with amylene hydrate was used in Dr Maddock's case, the associated anoxemia might well account for the postoperative disturbances shown. Any control of this anesthetic factor would be difficult, since even with local anesthesia the psychic stimulus of fright could operate to increase the content of epinephrine. It is difficult to accept the relationship between epinephrine and pulmonary edema. Freeman's studies on surgical shock indicate that the effect of increased production of epinephrine is dehydration. Congestion of the lung has been seen as a terminal development in thyroid crisis and it has appeared logical to explain it on the basis of cardiac failure. From the practical standpoint, genuine thyroid crisis is not encountered as frequently as a few years ago. The improvement can be attributed, as Dr Maddock and his co-workers have intimated, to various factors, the chief of which are surgery earlier in the course of the disease, careful preoperative preparation of the patient, and the administration during the immediate postoperative period of adequate amounts of fluid and dextrose. Six years ago I began giving to all severely toxic patients dextrose solution by continuous intravenous drip for several days after operation. In approximately 950 operations for toxic goiter at the Hospital of the University of Pennsylvania during these last six years, only two patients have developed crisis after operation and in one of these the dextrose routine was not followed. The benefits which patients obtain from this therapy are probably due to the provision of a readily available fuel and also to the correction of fluid balances. Accumulating evidence points to the fact that one does not restore the depleted glycogen content of the liver by simply administering dextrose, as it was originally believed that it was possible to do.

DR WILLARD BARTLETT JR., St. Louis. It may be recalled that last year before this section I reported the use of the continuous neutral bath for the treatment of thyroid crisis, thus, by providing the "engine" with a better "radiator," being able to separate the phenomena due to hypercombustion from those due to toxemia. The significant point is that some patients die in thyroid crisis even after an afebrile course in the neutral bath. A study of the variations in the blood amylase during the immediately postoperative phase discloses that the amylase drops sharply within eight hours of thyroidectomy for toxic goiter and stays at this low level for forty-eight hours, rising only slowly thereafter, the preoperative level may not have been regained at discharge on the fifth postoperative day. Enucleation of a nontoxic adenoma is not followed by any variation in the blood amylase. This quantitative method was developed by Somogyi and is considered to be the most delicate test of liver function that is available. Until evidence to the contrary is forthcoming, impaired liver function will have to be considered as responsible for some portion of the manifestations of thyroid crisis.

DR WALTER G. MADDOCK, Ann Arbor, Mich. Drs Crile, North and Bartlett have added to this interesting subject, and I wish to thank them for their discussion. Much more work will be necessary to establish the exact cause of thyroid crisis. I feel that I am just beginning on the question of epinephrine concentration being increased and I am looking forward with pleasure to further work on the same subject.

THE TRAINING OF THE STUDENT IN WHAT IS INVOLVED IN ADE- QUATE MEDICAL CARE

A. A. BAILEY, M.D.

AND

H. G. WEISKOTTEN, M.D.

SYRACUSE, N. Y.

During recent years there has been a feeling on the part of many medical educators that there has developed too great a tendency in the undergraduate curriculum to stress disease rather than the patient suffering from disease.

Although the discontinuance of the preceptorship and the institutionalizing of medical education was an important and necessary development, it did tend to emphasize to the student the details of disease processes and to minimize a consideration of the patient as an individual. Students became inclined to view patients more or less abstractly in terms of specific diseases, e. g., a case of pneumonia or a case of mitral stenosis.

The recent rapid advances in the physical and chemical aspects of medicine with the development of a large number of technical procedures useful in both the diagnosis and the treatment of disease have tended to submerge further a consideration of the patient as an individual reacting to a myriad of conditions of which the disease itself is but a part.

The successful practice of medicine requires an appreciation of the influence that heredity, social and environmental factors and individual peculiarities exert on the course of illness. As stated by Dr. Longcope,¹ "There is no separation of man from his disease or of disease from man. It is the patient and not the typhoid bacillus that presents to us the disease typhoid fever, it is the violently disturbed reaction of the patient to the abnormal action of the thyroid gland, not thyroxine, that gives us Graves' disease, and it is the more or less successful efforts of the patient to overcome a stricture of the mitral orifice, not the stenosis itself, that produces the picture called heart disease."

It is undoubtedly true that most physicians who enter the field of general practice eventually have these truths impressed on them. However, the nature of medical practice, especially in the more metropolitan areas, is changing to such an extent that personal and environmental factors do not stand out in bold relief as they do in the more intimate relationships of the "old time family doctor."

The psychiatrists have incorporated in the undergraduate curriculums of many schools courses in psychobiology to emphasize the importance of personality in the development of mental diseases. Other clinical teachers have been thereby stimulated to stress a consideration of patients as individuals. With the development of medical social work, certain schools have also included in the curriculum seminars and conferences between medical social workers and students.² In a few instances, students have been required to visit the homes of patients.

Our object in this paper is to describe briefly a procedure with which we at Syracuse have been experimenting since 1930 in the hope that it would give our students a better point of view toward all the problems involved in adequate medical care. The program was supported by a grant from the Josiah Macy Jr. Foundation. The procedure we adopted was suggested by Dr. Ira Hiscock, who had followed a somewhat similar plan in teaching public health. Our program has involved placing of responsibility on each student for a complete study of at least one patient who has been assigned to him as a clinical clerk on the hospital wards.

At the beginning, the home visits connected with these studies were supervised by the hospital social worker. However, it was our experience that such supervision tended to routinize the work of the student and failed to develop initiative and the coordination that was essential to a satisfactory point of view toward the case as a whole. After several years of experimenting the program has developed until it is now conducted as follows. Each clinical clerk is assigned a patient for investigation. The patient selected is one whom he has studied in the hospital from the clinical point of view. An effort is made to avoid cases in which the diagnosis is doubtful and to select those cases which present individual and environmental problems. The selection is made by an instructor in medicine who is on active duty in the medical ward. He also follows and directs the investigation by the student. The instructor may be aided by the social worker in the selection of the cases, but the student does not consult the social worker before making his study of the case.

The instructor explains to the clinical clerks the significance of the investigations and outlines to them a general plan of procedure. The student then visits the patient's home, interviews the family, surveys the situation in general and drafts a rough report, giving the results of his investigation. The instructor reviews this report with the student and then goes with him to the home and familiarizes himself with the situation. He then discusses with the student the problems presented and, if necessary, makes suggestions for further investigation. On the completion of his study, the student prepares a report which includes a series of recommendations with regard to the adequate handling of all aspects of the case. He presents this report at one of the medical seminars, which are held weekly throughout the year. The seminar is conducted by the professor of medicine and attended by the professor of bacteriology and public health, the professor of psychiatry, the professor of sociology in the university, the social workers from the outpatient department and the hospital, the instructor in charge of the students' investigations, and from four to six students.

After the student has presented his report, the social workers are asked to comment on the case and to give any additional information they may have. We have found that a discussion of the case by the social worker means more to the student at the time of the seminar than it would if held before he has completed his own investigation. Each faculty member then discusses the situation from his own particular point of view and questions the student with regard to various aspects of the case. The attending students participate in the discussion.

The student is expected to follow his patient throughout the year and to file a supplementary report giving

the final status of the patient at the end of the year. Usually two reports are presented at each seminar meeting and the schedule is so arranged that each student attends four seminars and thus hears the presentation and discussion of seven cases other than his own.

A brief review of a few of the many situations and problems discussed may be of interest.

The first case reported last fall was that of a 14 year old girl who died within a few weeks of *Streptococcus viridans* endocarditis. This child was a member of an ignorant Polish family and for years had been known to have rheumatic heart disease. She had attended medical clinics in the city but, either because of a lack of knowledge of the situation at home or because of a lack of contact between the medical agencies concerned and the family, the little patient had been woefully neglected. She lived in a cold, dump house and her clothing was entirely inadequate for the rigors of the winters through which she lived. She was frequently chilled and cold at home. No attempts were made to restrict her activities. She went to school thinly clothed and walked through snow and slush in shabby shoes and sat for hours in school with cold, wet feet. Her teeth were neglected and abscesses developed. Obviously diseased tonsils were disregarded. Her diet was frugal. Doubtless the family was informed after medical examinations in school or in the clinic, that the patient should not run and play as other children, that she needed dental care, perhaps tonsillectomy, surely a better balanced diet and warmer clothing. But, because of a lack of intelligent contact with the family and, too, because of their ignorance, they were not made to understand the seriousness of the situation and the recommendations were not carried out and the neglect continued. With such conditions, the development of the endocarditis could almost have been predicted. This type of case provides a dramatic illustration of the importance of environment in the development of disease.

Another case was that of a woman of 38, admitted to the hospital because of having attempted suicide. Investigation revealed that she was a prostitute springing from a background in which were sprinkled insanity, immorality, alcoholism and criminal traits as far back as the grandparents. As a child, she was beaten and locked in closets. She attempted suicide first at the age of 14. She feared and hated her relatives. Sexual immorality began at 18. After her marriage at 19 she became alcoholic and left her husband after a short time. She had been a professional prostitute for about seven years. Yet this alcoholic, suicidal psychopath could not be called insane, so neither the Department of Mental Hygiene nor any other state or local agency had any provision for her but to allow her to continue her existence unchanged—a miserable, unhappy example of what poor, weak-minded degenerate families may produce if society refuses to help and guide them.

A somewhat more dramatic case illustrating that the responsibility of a physician does not end when he has made the diagnosis and instituted the proper treatment, was that of a middle-aged man who was found to have pernicious anemia. A correct diagnosis had been made and proper treatment instituted by a private physician. The patient had returned once or twice for observation and then failed to appear. When last seen by his physician, the anemia had been relieved

and the patient had no complaints. About three months later, however, the patient returned, a helpless cripple, markedly anemic and unable to walk because of advanced changes in the spinal cord. He had discontinued the treatment and, of course, his anemia had reappeared and, unfortunately, the spinal cord lesions had developed. It was thus evident that the physician's skill in diagnosis and his knowledge of therapeutics were wasted because he failed to ascertain why it was that his patient did not return. Our students are now being taught that the responsibilities of a physician make it necessary for him to ascertain that his patient is receiving proper medical attention before he allows him to be lost sight of. Some may object to this point of view and say that the physician is not responsible for what may happen to a patient who refuses to cooperate with the advice given, but if the physician has the best interests of his patient at heart he will reply to this objection by saying that lack of cooperation on the part of a patient merely increases the difficulty of the problem at hand, as such behavior is to be considered symptomatic of some mental disturbance or due to some environmental factors which the physician must search for and correct.

Other cases illustrate the influence of poverty, emotional conflicts and religion on the development and progress of disease. In some instances, psychoses or impending psychoses not recognized by the clinical studies in the hospital were brought to light by the student's investigations of the patient's life at home and in the community. Patients requiring continued medical care at home because of their inability, for various reasons, to attend medical clinics are frequently encountered.

Students are frequently brought into contact with various health, welfare and religious agencies and learn how they are prepared to assist the physician in the care of the patient. They also come to realize that the physician himself becomes a part of the patient's environment and that his attitude toward the patient is always important. He learns that he must study the individual with whom he deals, attempt to get his point of view, find out his understanding of his illness—what he may fear, what he may disregard—and gain his friendship and confidence. Only when a physician has done this and, in addition, has familiarized himself with the peculiarities of the environment and the other members of the family may he intelligently advise the patient and expect his advice to be heeded.

The professor of medicine who has been in charge of the seminars since their inception feels that they have developed into one of the most valuable exercises in the entire curriculum, involving as they do an integration of preventive medicine, psychiatry and the social aspects of medicine in the study of the individual patient. The professor of pediatrics was much impressed by this program and has for several years required similar home visits by students during the period of their clerkship in the pediatrics wards. He feels that these visits are of great teaching value and that they frequently result in an entirely changed point of view as to the proper handling of the case.

As a result of these experiences, our students now graduate with an appreciation of the many problems involved in the practice of medicine and they are also better prepared to assume intelligent leadership in connection with modern social trends as far as they affect adequate medical care.

THE INTRATHECAL USE OF PRONTOSIL SOLUBLE

REPORT OF A CASE OF TYPE III PNEUMOCOCCUS MENINGITIS AND SEPTICEMIA TREATED WITH PRONTOSIL SOLUBLE, WITH COMPLETE AUTOPSY REPORT

JOSEPH MILLETT, MD

Resident Physician, Meadowbrook Hospital
HEMPSTEAD, N. Y.

Since the introduction of the original prontosil by Domagk¹ as a therapeutic agent against hemolytic streptococci in mice, its two derivatives prontosil soluble and sulfanilamide have been extensively used against a variety of infections in man.

Experimental evidence by Rosenthal,² by Cooper, Gross and Mellon³ and by Cooper and Gross⁴ show that sulfanilamide has distinctly therapeutic properties in rats and mice infected with the type III pneumococcus. Heintzelman, Hadley and Mellon⁵ reported a small series of nineteen cases of type III pneumococcus lobar pneumonia, which carries a high mortality in the Pittsburgh area. Of nine patients who received sulfanilamide, seven lived and two died, while of the remaining untreated patients eight died and two recovered. At the Meadowbrook Hospital⁶ a crisis was induced by sulfanilamide twenty-four hours after onset of a type III lobar pneumonia, which was contrary to our experience with the disease over a period of two winters since the establishment of the hospital.

Prontosil soluble given parenterally, intramuscularly or subcutaneously is rapidly absorbed. Long and Bliss⁷ noted its appearance in the urine within fifteen minutes after subcutaneous injection and discouraged its use intravenously both because it is unnecessary and because of its toxic effects. Colebrook and Kenny⁸ also advised its intramuscular or subcutaneous rather than its intravenous use.

The intrathecal use of prontosil soluble has received scant attention. Schwentker and his associates⁹ used prontosil soluble intrathecally in one of their cases of streptococcal meningitis with untoward effects, the temperature rising to over 106 F with irritation of the meninges and a marked cellular reaction. They advise the use of crystalline sulfanilamide 0.8 per cent in physiologic solution of sodium chloride for intrathecal use. If the crystalline compound cannot be obtained, they advise the use of prontosil soluble subcutaneously and sulfanilamide by mouth. The experience of

Schwentker with prontosil soluble was not borne out in a case of streptococcal meningitis treated at Meadowbrook Hospital, with recovery,¹⁰ when 60 cc of prontosil soluble was administered intrathecally in three divided doses of 20 cc each over a period of twenty-four hours. Within twenty-four hours the count dropped from 5,000 cells with 75 per cent polymorphonuclear leukocytes to 1,700 cells with 75 per cent polymorphonuclears, and twenty-four hours after that the count was 280 cells with only 32 per cent polymorphonuclears. Sulfanilamide was also given by mouth and prontosil soluble intramuscularly. In the case of type III pneumococcus meningitis and septicemia here reported, prontosil soluble was given intramuscularly and intrathecally.

REPORT OF CASE

A white woman, aged 53, in a good state of nutrition, was disoriented, irrational and uncooperative on admission. The history was obtained from her husband. For about ten days previous to admission the patient had had a moderate cold in the head. The day before admission the patient boarded a train for New York City 20 miles away and, while riding, suddenly became sick, complained of marked headache and malaise and vomited. She returned home unassisted and went to bed, complaining of a severe diffuse headache. She was oriented and cooperative all that night, but her husband noted "convulsive twitchings" of the extremities and face. She was seen by her physician, who prescribed palliative treatment and returned to see her the next morning. At this time he noted definite meningeal signs and disorientation and advised hospitalization.

The past history was essentially negative aside from an occasional discharging right ear.

Physical examination revealed a temperature of 104 F rectally, the pulse was 120 and the respiration rate 35. The pupils were round and equal. It was impossible to elicit extraocular movements. The ear drums were normal except for a scarred right drum with a small central perforation. No discharge was noted. The pharynx was normal. The neck was markedly rigid. The chest was clear and the heart normal. There were positive Kernig and Brudzinski signs but no Babinski reflex was obtained.

The urine was of good concentration, 1 plus albumin, and from 8 to 10 red blood cells and from 10 to 12 white blood cells were noted (catheterized specimen). The hemoglobin was 72 per cent, leukocytes 18,500, polymorphonuclears 85 per cent and lymphocytes 15 per cent. The Wassermann and Kahn reactions were negative.

A spinal tap revealed thick greenish pus, which flowed fairly easily and separated into two layers almost immediately in the test tube. Because of the character of the fluid, specific treatment was withheld until the fluid was examined. A smear revealed many gram positive diplococci, which proved to be type III pneumococci. The cell count was over 18,000, with 99 per cent polymorphonuclear leukocytes. The spinal canal was again tapped and drained and 20 cc of prontosil solution 2.5 per cent was instilled, and 20 cc was given intramuscularly. Six hours later a spinal tap was done for drainage. Dr. Jasper of the ear, nose and throat service was called in consultation. His opinion was that the meningitis was probably secondary to infection of the ethmoid and sphenoid sinuses in view of the history of infection of the upper respiratory tract preceding the present illness. Roentgenograms of the skull and sinuses revealed marked ethmoiditis, chronic maxillary and frontal sinusitis and an enlarged sella turcica, with erosion of the floor and posterior clinoid process. Because of the patient's desperate condition, drainage of the ethmoid and sphenoid sinuses was advised. A submucous resection, bilateral middle turbinectomy and opening of the sinuses were performed. The patient's condition remained unchanged.

Later that evening a cisternal tap was done and 65 cc of fluid the color of prontosil was removed. Twenty cc of

From the Medical Service of Dr. Ernest Dickey.
The prontosil soluble solution used in this case is the solution marketed as "Prontosil Solution 2.5 per cent" by the Winthrop Chemical Company. The term prontosil has regrettably been used in the literature for a number of related substances. To avoid confusion the term prontosil used in this paper refers to prontosil solution 2.5 per cent which according to the label is disodium 4-sulfamido phenyl 2-azo 7-acetyl amino 1-hydroxynaphthalene 3,6-disulfonate.

prontosil solution was injected intrathecally in the lumbar region and 20 cc was given intramuscularly. At 2:30 a.m. the spinal tap was repeated and 20 cc of the prontosil was given intrathecally and intramuscularly again. The patient's condition was extremely poor. At 10 o'clock the temperature rose to 106.4 F and while a spinal tap was being performed the patient died, twenty hours after admission.

Culture of the blood taken on admission was reported to have too many colonies of type III pneumococci to count. Culture of the spinal fluid (initial tap) contained numerous type III pneumococci. The next day the culture of the spinal fluid, which was made from the spinal fluid taken at the last tap, was reported to have only a scant growth of pneumococci.

Permission for complete necropsy was obtained.

The entire body was observed to have a pinkish hue. When the skull cap was removed the dura was found to be homogeneously stained red. When the dura was removed the entire brain and leptomeninges were found to be stained in the same manner. The brain was removed in the usual manner and the entire base was found to be, as far as the naked eye could tell, entirely free from pus. The most remarkable finding was a large pituitary tumor, which was quite soft and which oozed pus on attempted removal. The petrous portion of the temporals was normal and the ethmoidal and sphenoidal sinuses were found to be filled with a small amount of postoperative blood. Microscopic examination of the organs revealed nothing of any moment that could not be attributed to the infection. There was no evidence of what might be considered chemical irritation of the brain cortex, and the leptomeninges showed a moderate degree of inflammation.

COMMENT

This patient died of an overwhelming infection of the type III pneumococcus. There is some experimental and clinical evidence which, although meager, points to the fact that sulfanilamide has some therapeutic action against the type III pneumococcus. The initial spinal tap in this case contained an abundance of type III pneumococci, the pus was fairly thick and greenish and the cell count was high, yet a culture taken after the administration of 60 cc of prontosil soluble intrathecally revealed only a scant growth of the organism. Unfortunately no cell count was made on this specimen.

The necropsy revealed that prontosil soluble administered intrathecally diffuses generally throughout the central nervous system with apparent ease and a minimum of irritation. It does not affect subsequent drainage and mixes intimately with the spinal fluid.

Because of the condition of this patient, sulfanilamide in tablet form was not given. The question was brought up as to whether or not prontosil soluble injected intramuscularly had any effect on sterilizing the spinal fluid. In order to find out whether there was any diffusion of the dye into the spinal canal, the following experiment was performed on an adult male volunteer.

At 2:30 p.m. 20 cc of prontosil soluble was injected intramuscularly into the buttock. In fifteen minutes the urine excreted was colored red. One-half hour after the injection a needle was inserted into the spinal canal and varying amounts of fluid were withdrawn every fifteen minutes. At 3:30 20 cc more of prontosil soluble was injected intramuscularly. By 4:30 about 60 cc of colorless, unstained spinal fluid had been removed. The needle was withdrawn and reinserted at 7:30, but the fluid was still colorless, although the patient had assumed a faint but definitely pink color throughout.

No chemical or bacteriologic studies were made on the specimen of spinal fluid to observe whether or not the fluid contained sulfonamide radicals or was bactericidal. It is interesting to speculate why the glomerulus, but not the choroid plexus, will excrete the dye so quickly.

SUMMARY

1 Prontosil soluble has been used intrathecally with marked bactericidal effect on type III pneumococcus meningitis in a patient who died of type III pneumococcus bacteremia.

2 Postmortem examination of the brain both grossly and microscopically revealed no apparent chemical injury due to the drug.

3 Because of its proved diffusibility throughout the central nervous system, prontosil soluble is recommended for intrathecal medication, augmented by the oral use of sulfanilamide, in those meningeal infections which have been shown to respond to these compounds.

Clinical Notes, Suggestions and New Instruments

STREPTOCOCCIC BACTEREMIA AND APPARENT THROMBOSIS OF THE CAVERNOUS SINUSES WITH RECOVERY

WARD J. MACNEAL, M.D. AND MICHAEL E. CAVALLO, M.D.
NEW YORK

In recent medical literature there have been increasingly frequent reports of the successful care of patients afflicted with infections formerly regarded as almost certainly fatal. So far as we are aware, however, recovery of a patient with bacteremia accompanied by evidence of obstruction in the cavernous sinuses still remains a medical rarity. Cavenagh¹ was able to find only seven reported recoveries from acute thrombosis of the cavernous sinus. Three patients recovered after surgical drainage of the sinus and of these only one had a positive blood culture (*Staphylococcus aureus*). Four patients recovered after anti-infective therapy. Three of these cases were due to *Staphylococcus aureus*, and this organism was recovered from the blood stream in two of the patients. One of these patients with bacteremia received only transfusions. The other two patients were treated with bacteriophage. The fourth patient in this group given anti-infective therapy appears not to have had a positive blood culture. He was given polyvalent anti-streptococcus serum intravenously. Cavenagh found also a record of one instance (Seale's case) of spontaneous recovery in an African native without bacteriologic study or specific treatment.

Grove² reports an instance of thrombosis of the cavernous sinus of septic origin, after operation on the mastoid. The patient recovered. The author expressed the opinion that the thrombosis in this case occurred in a retrograde manner from the lateral sinus or from one of the petrosal sinuses and that the thrombus in the cavernous sinus itself was sterile. He was unable to conceive of recovery taking place when the thrombus within the cavernous sinus itself was infected. Apparently there was not a bacteremia in this case. Two other recoveries reported by this author were evidently examples of aseptic thrombosis of the cavernous sinus following severe trauma. Grove concludes that in the septic types in which the thrombosis or thrombophlebitis reaches the cavernous sinus by way of its afferent vessels the mortality is practically 100 per cent.

The case about to be discussed presented roentgenologic evidence of pansinusitis, a positive blood culture, severe cyanosis of the face, enormous engorgement of the veins of the forehead and eyelids, marked chemosis of the conjunctivae including the right cornea and proptosis on both sides but especially marked on the right. A clinical diagnosis of septic

From the Department of Pathology and Bacteriology and the Department of Surgery, New York Post Graduate Medical School and Hospital, Columbia University.

thrombosis of the cavernous sinuses was made. The principal evidence against this diagnosis is found in the outcome of the disease.

REPORT OF CASE

K. C., a white woman, aged 40, a housewife, admitted to the hospital April 15, 1937, complained of fever, vaginal bleeding and swelling of the face of three days' duration. Marked swelling of the left eyelid began April 13 and similar swelling of the right eyelid April 14. A severe laryngitis had been present from April 8 to April 15. On admission the forehead, the malar regions, the bridge of the nose and the left side of the face and neck were red, swollen, tender and hot. The left eye was swollen shut. The right eye was two thirds closed and the eyeball protruded. Vaginal bleeding was moderate. Examination of the lungs was negative. The patient could speak only in a whisper and there was some mental confusion, apparently febrile. The temperature on admission was 102 F., pulse 78, respiration rate 24. X-ray examination, April 16, by Dr. William H. Meyer revealed veiling of both antrums and the ethmoid and sphenoidal sinuses, and he made a diagnosis of pansinusitis. Blood culture taken April 16 yielded positive growth of hemolytic streptococci both in broth flasks and in the agar plates. April 16 the right eye closed entirely. Mental confusion increased, with periods of delirium

only partly translucent. The eyeball was displaced forward. During a lucid interval the patient evidently could distinguish light and shadow with this eye but she could not count fingers. The left eye was in general similar but here the cornea remained clear with a puffy scleral conjunctiva elevated all about its margin. The patient could count fingers with this eye when it was held open for her. At this time the diagnosis was septic thrombosis of the cavernous sinus, bilateral, more severe on the right side, nasal pansinusitis, streptococcal bacteremia, early pneumonia of the right lower lobe, cyanosis in part due to alteration of blood by sulfanilamide. An unfavorable prognosis was given to the family.

Antistreptococcus serum,³ 0.05 cc, was injected into the skin of the left forearm at 11 06 a. m. and 1 cc diluted with an equal volume of saline solution was injected subcutaneously. A second subcutaneous dose of 15 cc of serum was given at 11 25. The next dose, 1 cc of serum plus 1 cc of saline solution, was given into the triceps muscle at 11 45, and at 12 15 noon another intramuscular injection containing 15 cc of serum was given. At 12 35 the first intravenous dose was given, 0.05 cc of serum diluted with 0.95 cc of saline solution, and this was followed by increasing amounts of serum intravenously, 0.15 cc at 1 17 p. m., 0.3 cc at 1 35, 0.5 cc at 2 05, 1.5 cc at 2 43, 2.5 cc at 3 10, 5 cc at 3 47 and 6.5 cc at 4 13,

making a total of 21.5 cc of streptococcus serum for the day. In each instance the serum was suitably diluted with salt solution so as to be injected through a fine needle, gauge 27, for the intravenous doses. At 3 50 p. m. the patient was able to count fingers with the right eye when it was held open by the examiner.

Monday, April 19, the patient seemed much brighter and was inclined to chat cheerfully with the nurse. At 8 30 a. m. she could see clearly with either eye. At 9 20 a. blood culture was taken, which remained sterile. A bedside spectroscopic examination of the blood at this time was negative for methemoglobin and on this account, even though the patient was still very cyanotic, we felt that there was still enough functioning hemoglobin to provide a margin of safety permitting the administration of further sulfanilamide in 5 grain doses every four hours. April 19 a total amount of 25 cc of streptococcus serum was given in three intravenous injections and on subsequent days 30 cc. a day in three intravenous injections until April 25, when the amount was reduced as shown in the accompanying chart. All serum was given intravenously after the first day, April 18.

Pain in the right thorax became very severe April 21 and the respiratory rate reached 46 per minute. A distinct pleuritic friction sound could be heard below the breast in the anterior axillary line. This side was therefore taped and the adhesive strips were left on until April 24, at which time the pleuritic pain had disappeared, apparently without any marked effusion. The dose of sulfanilamide by mouth was increased to 10 grains every four hours April 21. The patient rebelled against this, ascribing to it her nausea and vomiting, and April 25 she took only half the dose at 6 15 p. m. The sulfanilamide was discontinued entirely April 29. The patient was still very cyanotic, although it was impossible to detect signs of pleural effusion or of pneumonic consolidation. The respiration rate continued to be about 30 per minute. A spectroscopic test of the blood was negative. After this drug was stopped the color of the patient gradually changed so that on May 3 she presented the skin and pink mucous membranes of a pronounced blonde. The nausea also disappeared. Untoward effect of the serum was evidenced by urticaria April 23, becoming more severe April 26. The dose of serum was reduced as shown in the chart.

3 The polyvalent concentrated antistreptococcus serum biologic no. 102 2005 of Parke, Davis & Co. was employed throughout for this patient.

Abridged clinical record of K. C. a white woman aged 40. Temperature, pulse and respiration rate are shown by the graphs. April 16, x-ray examination showed pansinusitis. Blood culture taken on this day yielded positive growth of hemolytic streptococcus. Sulfanilamide 10 grains every four hours by mouth was started that evening. It was discontinued April 17 given again in 5 grain doses beginning April 19 and increased to 10 grain doses April 21 and finally discontinued April 29. Streptococcus serum was given in multiple doses April 18 and thereafter every day until discharge from the hospital. Specific streptococcus bacteriophage in the asparagin medium was given intravenously April 27 and continued until discharge. Fractional transfusions were given May 5 to 9. Very marked cyanosis persisted until April 30 when it rapidly disappeared. Spectroscopic examination of the blood for methemoglobin however was negative April 19, 20 and 29.

Sulfanilamide, 10 grains (0.65 Gm.) every four hours by mouth, was started at 9 30 p. m. Friday April 16. Dyspnea and cyanosis increased progressively. April 17 the patient refused to take any more sulfanilamide because of nausea. Paroxysmal pain in the right thorax and coughing spells associated with severe cyanosis, as well as a moderate persistent cyanosis, were now present, and there was distressing pain and marked tenderness of the entire right upper extremity. During the night of April 17 she was delirious and quite noisy until the condition was controlled by hypodermic medication.

Sunday morning, April 18, her condition appeared desperate. There was very marked cyanosis and edema of the forehead, eyelids and upper part of the face and a less marked general cyanosis. The patient could not open her eyes. On the edematous upper lids the distended veins stood out as tortuous ridges from 2 to 3 mm in diameter. On the swollen forehead distended tortuous veins radiated upward from the inner angles of the eyes, and along the borders of these engorged veins were numerous minute capillary hemorrhages in the skin. The patient was a natural blonde with light auburn hair, but her facial skin was a blue gray. When the upper right eyelid was raised by the examiner, the conjunctiva was everywhere thickened by translucent edema and the cornea was irregularly thickened and

Meanwhile the efforts directed to the preparation of a specific bacteriophage had succeeded in the production of a lytic filtrate capable of causing satisfactory lysis of the patient's streptococcus in the test tube. This preparation was given by intravenous injection, beginning April 27 and continued as shown in the chart.

Continued low fever and a dull headache in the right frontal region made us fearful of a persistent intracranial complication. However, the headache disappeared. The dilated veins on the forehead and on the eyelids gradually returned to normal. Small hemorrhagic spots persisted along the courses of the veins on the forehead for a time, but these also had disappeared by May 15. The administration of blood from May 5 to 9 inclusive seemed to help the gain in strength. The patient was up and about after May 15 and was discharged from the hospital May 29. Because of the fact that the rectal temperature still continued to reach from 99.4 to 99.8 F each day, she was advised to continue temperature observations at home. Reports indicate that a day of unusual effort is followed by a rise in temperature to 99.8 or 100 F, although she feels quite well in other respects.

In reporting this case we are well aware that we are not offering critical evidence to aid in deciding an argument about the therapeutic efficiency of the sulfonamides of streptococcus serum or of streptococcus bacteriophage and we would disclaim any immediate interest in exploiting any of these agents. Rather, it is our intention and our hope that this report may bring some encouragement and perhaps assistance to the conscientious physician confronted with the problem of caring for a patient desperately ill with streptococcal bacteremia and evidence of obstruction in the cavernous sinuses.

303 East Twentieth Street

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

GITALIN (AMORPHOUS)—A glucosidal constituent of *Digitalis purpurea* Linne prepared according to the method of Kraft. It is standardized by the intravenous cat method of Hatcher and Brody (*Am J Pharm* 82:360, 1910) and its potency adjusted to an M. L. D. of 0.8 mg per kilogram of body weight.

Actions and Uses—The same as those of digitalis.

Dosage—Full digitalis effects are usually obtained after a total dosage of $\frac{1}{40}$ to $\frac{1}{20}$ grain, or from five to eight tablets. These effects may be obtained by the administration of two to three tablets per day for three or four days. The same precautions should be taken with gitalin as with any digitalis preparation or digitaloid drug. Should toxic symptoms, such as nausea or vomiting occur during the course of digitalization administration of the drug should be discontinued. After the desired clinical effects have been induced, the patient may be placed on a maintenance dose of $\frac{1}{240}$ to $\frac{1}{40}$ gram (one-third to one tablet) daily. The amount varies according to the individual requirements of the patient. Gitalin (amorphous) is less cumulative than digitoxin but more so than ouabain and most tinctures of digitalis. While the biologic cat unit has been determined to be 0.8 mg ($\frac{1}{40}$ grain) per kilogram of body weight, gitalin (amorphous) apparently gives good clinical results in amounts ranging from one-third to one-half the dose calculated on this basis.

Manufactured by Rare Chemicals Inc., Nepera Park, N. Y. No U. S. patent or trademark.

Tablets Gitalin (Amorphous) 0.8 mg ($\frac{1}{40}$ grain). Each tablet is scored into segments of $\frac{1}{40}$ grain for convenience in regulation of the daily maintenance dose.

Dried and ground leaves of *Digitalis purpurea* Linne are extracted with cold distilled water. This aqueous infusion is then treated with basic lead acetate and the lead subsequently removed by precipitation with sodium sulfate. The resulting filtrate is agitated with chloroform and allowed to separate. From the chloroform extract the gitalin

(amorphous) substance is precipitated by means of petroleum ether. The precipitate is subjected to further purification and finally dried in vacuo. The entire process of extraction and purification is conducted without the aid of heat.

Gitalin (amorphous) is a white or slightly buff colored amorphous powder which is readily soluble in chloroform, ether, acetone and alcohol and is slowly soluble in 600 parts of cold water. It is insoluble in petroleum ether and carbon disulfide. Its aqueous solution is neutral to litmus and possesses an intensely bitter taste. It has no sharp melting point but undergoes some decomposition when heated to 110 C and becomes fluid as the temperature is raised to 150 C. When its aqueous solution is boiled gitalin (amorphous) is converted into anhydrogitalin with a subsequent loss of about 30 per cent in potency.

Dissolve 10 mg of gitalin (amorphous) in 3 cc of glacial acetic acid in a narrow test tube and add to this one drop of 5 per cent ferric chloride solution. Underlay this solution with concentrated sulfuric acid. A brownish red zone appears at the point of contact. The upper acetic acid layer assumes a bluish green color gradually changing to indigo blue. Repeat the test without the addition of ferric chloride. A brown zone appears at the point of contact and the upper acetic acid layer remains green. Concentrated sulfuric acid containing 10 mg of gitalin (amorphous) and a trace of ferric chloride produces a brown color gradually changing to red and finally to violet. When an aqueous solution of gitalin (amorphous) is heated for one hour at 100 C its potency is reduced 30 per cent. This latter drop is a characteristic feature of gitalin (amorphous) and is due to the conversion of gitalin into anhydrogitalin. It does not occur with digitalein or digitoxin.

SILVER PICRATE-WYETH'S (See *THE JOURNAL*, July 3, 1937, p. 29, Supplement to New and Nonofficial Remedies, 1937, p. 16).

The following dosage form has been accepted:

Silver Picrate Liquid Suppositories 1 grain (infant size) Silver picrate N. N. R. in a boroglyceride gelatin base.

STAPHYLOCOCCUS TOXOID (See New and Nonofficial Remedies, 1937, p. 405).

E. R. Squibb & Sons, New York.

Staphylococcus Toxoid Squibb—Prepared by growing cultures of *Staphylococcus albus* and *Staphylococcus aureus* in semisynthetic mediums for forty-eight hours at 37 C in a special container containing 80 per cent carbon dioxide and 20 per cent oxygen. The toxin is detoxified by treating with 0.3 per cent solution of formaldehyde. U. S. P. and held at 37 C until 0.2 cc causes no necrosis when injected intradermally into rabbits. Merthiolate 1:10,000 is added. The finished material is passed through a Berkefeld filter and tests according to the regulations of the National Institute of Health are made to determine sterility. In addition potency and safety tests are made. George F. Leonard and August Holm (*J. Immunol.* 29:209 [Sept.] 1935) give a full description of the process of preparation and testing. The product is tested for sterility by planting in appropriate mediums according to the regulations of the U. S. Public Health Service for testing the sterility of biologic products. Safety tests are made by injecting 5 cc subcutaneously into guinea pigs and 0.5 cc intraperitoneally into white mice. The antigenicity of staphylococcus toxoid is determined by injecting 1 cc of toxoid per kilogram of rabbit intravenously into three rabbits and the resulting serum is tested at the end of one and two weeks for its content of staphylococcus antitoxin. No staphylococcus toxoid is used which in doses of 0.2 cc or less of the undiluted material will cause necrosis when injected undiluted into rabbits. The toxin is titrated to determine its dermonecrotic activity and also its actual killing power in rabbits.

Staphylococcus toxoid Squibb is marketed in packages of one 5 cc rubber capped vial each cubic centimeter containing the toxoid derived from at least 1,000 necrotizing doses of toxin.

SCARLET RED SULFONATE (See New and Nonofficial Remedies, 1937, p. 196).

Scarlet Red Sulfonate—"National"—A brand of scarlet red sulfonate N. N. R.

Manufactured by The National Aniline & Chemical Co. Inc. New York. No U. S. patent or trademark.

LIVER EXTRACT-ARMOUR—A yellowish granular powder containing a water-soluble fraction extracted from fresh mammalian liver. The daily oral administration of 14 Gm (three vials) has been found to produce the standard reticulocyte response as defined by the Council when assayed in cases of pernicious anemia.

Actions and Uses—Liver extract-Armour is proposed for use in the treatment of pernicious anemia. See general article Liver and Stomach Preparations, New and Nonofficial Remedies, 1937, p. 309.

Dosage—Liver extract-Armour is administered orally. The average daily dose during relapse is three teaspoonfuls (or three vials). In severe and complicated cases, larger doses may be required.

Manufactured by Armour and Company, Chicago. No U. S. patent or trademark.

Liver extract-Armour is made by the process developed by Dr. K. K. Koeber and his co-workers Drs. M. T. Hanke and Siegfried Maurer in the laboratory of the Ohio State Sprague Memorial Institute at the University of Chicago. Fresh livers still retaining the animal heat are finely minced and macerated with three volumes of water. The coagulable proteins are removed by heat and the liquid is condensed at low temperature and negative pressure. The resulting extract is treated with hot 70 per cent alcohol under a reflux condenser and the soluble fraction separated by filtration. The clear filtrate is evaporated to dryness in vacuo and the residual extract dried and powdered.

WORLD HEALTH AND THE LEAGUE OF NATIONS

The menace to health and the danger from epidemics in war-torn China have already given much concern to health authorities throughout the world. Thus the Assembly of the League of Nations has voted two million Swiss francs to assist China in dealing with its health problem. October 14, according to a press release, the Subcommittee for Technical Cooperation with China was given a description of the present epidemic situation in that country. With regard to cholera, the report states, measures now in force, plus the onset of the cold season, justify the hope that a large-scale epidemic will not break out this year. There is, however, grave reason to fear a fresh pandemic during the spring and summer of 1938. The report continues:

It would not seem that the present disturbances are likely directly to influence the incidence of plague. Nevertheless, indirect repercussions, which might become serious internationally as well as nationally, are to be expected if the disturbances cause a breakdown in quarantine services and thus lead to the transmission of plague infection by sea.

If military operations should extend—particularly during the winter—to the Shansi-Shensi region, where plague is endemic, an outbreak of pneumonic plague might be feared as a dangerous contingency.

Any movement of refugees, carrying lice and the plague virus, toward the central, and more particularly the southern, parts of China, where the population is now immunized against typhus, is likely to lead to epidemics, at any rate on a local scale.

Any considerable shift of population may cause outbreaks of smallpox, by spreading infection among the rural populations, who include a high percentage of receptive individuals.

The difficulties of supplying clean water, both to troops on the march and to refugees outside camps are also clearly capable of causing a considerable increase in infections of the digestive tract, of the typhoid and dysentery types—the latter more especially during the hot season.

Meningitis is obviously more to be feared among the troops, by reason of overcrowding and fatigue among soldiers who are generally highly vulnerable to infection. Preventive measures are particularly difficult to take in times of war.

The situation as regards diphtheria and scarlet fever is very similar, and the same factors are likely to facilitate the spread of these diseases.

The diseases enumerated above do not exhaust the list of possible epidemics which may result from the military opera-

tions in China or from their repercussions. Mention may also be made of the probable increase in the incidence of venereal disease and the possible appearance of malaria epidemics, if troops or groups of refugees not previously immunized by infection remain in malarial districts during the hot season.

It is hardly necessary to refer to the increase in infant mortality and tuberculosis, which are inevitable consequences of the distress caused by war, even when actual famine does not occur.

The United States Public Health Service has also taken official notice of some of the problems raised by the Far Eastern carnage. In *Public Health Reports* for September 24 is a brief discussion of cholera in China.¹ The chief quarantine officer detailed to this duty by the United States Public Health Service in the Philippine Islands has directed all quarantine officers to carry out careful inspection of ships, passengers and crew from infected or suspected ports, including examination for carriers. It is believed, however, that the seaports on the western coast of the United States are not likely to become infected since the incubation period of cholera is only five days, and outbreaks on shipboard will occur before these ships reach any United States seaport. Air travelers from the Far East will also have completed the incubation period by the time they reach San Francisco, but those stopping off en route will be held at stopover points to complete the incubation period.

The importance of investigations and technical advice from the Health Organisation of the League of Nations to countries in sanitary difficulties has already been demonstrated several times. Thus the Report on the Health Mission in Spain,² of Dec. 28, 1936, to Jan. 15, 1937, while not disclosing as serious a sanitary situation as may be expected in China, was nevertheless a valuable review of the sanitary, housing and feeding problems associated with the civil war in Spain. MacKenzie³ has recently pointed out that there are four main activities of the League Health Organisation. These may be classified as the commissions and committees of experts, collaboration with various governments, the collection of information from various countries with regard to disease incidence, and medical educational work, including collective study tours, individual study tours and international courses in public health subjects. The functions of some of the commissions, notably those on malaria, leprosy and cancer, are quite generally known. The commissions on permanent standards, maternal welfare, medical education, treatment of rabies and others are also making important contributions. The Epidemiological Intelligence Service first began work in 1921. The information received is included in a bulletin which is telegraphed weekly, in a special code to the Geneva center and to certain eastern health authorities. Not the least important of the functions—

1 Cholera in China. *Pub. Health Rep.* 52: 1341 (Sept. 24) 1937.
2 Bulletin of the Health Organisation. League of Nations. Geneva G. 56 (Feb.) 1937.
3 MacKenzie, Melville D. Some Aspects of the Health Organisation of the League of Nations, *J. Malary Branch Brit. M. A.* 1: 6 (Jan.) 1937.

of the Health Organisation is the promotion of conferences on special subjects. As MacKenzie says, the rapidity of modern transport and the greater amount of traveling by all classes have increased the need for international collaboration, if the fullest possible advantage is to be taken of the available knowledge and experience in the control of ill health.

The immunologist Thorvald Madsen⁴ in the Harvey Lecture, February 18, spoke convincingly of the value of the scientific work of the Health Organisation. One of the difficulties in interpreting the public health statistics which the organization has attempted to collect and collate has been the establishment of uniform figures. Much must be done to make the data comparable on such questions as stillbirth, population estimates, and the notification of joint causes of death. In order to achieve the necessary uniformity and comparability, it was necessary to create several commissions of statistical experts who have studied the questions and made definite proposals to the health administration. The ultimate effect of this particular study should tremendously enhance the value of comparative medical statistics. As an instance of the practical value of some of the investigations, Madsen cites the investigation on the epidemiology of tuberculosis which was made in the three Scandinavian countries in 1925 and which showed the different manner in which tuberculosis has developed in these countries. In Denmark, for instance, tuberculosis has been spreading for a hundred years. This is probably one of the reasons it is now decreasing rapidly. Practically the whole population in all parts of Denmark have been infected and hence many persons are immune, whereas in Norway and Sweden the spread to remote parts has taken place more recently, and the tuberculosis rate has shown a tendency to rise until the last few decades.

GERIATRICS—THE CARE OF THE AGED

Geriatrics is a term, inclining toward general adoption, for that division of medicine which deals with the treatment of the diseases and special problems of old age and senescence¹. Between 1900 and 1930, Horn² says, there was an increase of 52 per cent in the actual numbers of those 60 years of age and over, compared with an increase of only 38 per cent in the total population. According to present trends, therefore, by 1990 the senescent population will have become equal to, if not in excess of, the preadolescent population. Furthermore, disease in old age differs in many ways from disease in younger groups, the incidence is different and the symptoms often diverge widely from those seen in middle and early life.

⁴ Madsen Thorvald. The Scientific Work of the Health Organisation of the League of Nations. *Bull. New York Acad. Med.* 13: 439 (Aug.) 1937.

¹ Giese C. L. *Geriatrics*. *Colorado Med.* 29: 159 (April) 1932.
² Horn Will S. *Geriatrics as a Modern Specialty*. *Texas State J. Med.* 33: 448 (Oct.) 1937.

The diseases of old age which call for medical attention may be divided roughly into two types: those which also occur in younger years and those which are definitely characteristic of the degenerative processes inherent in continued living. Pepper³ has pointed out some important features. The stomach is a frequent seat of cancer in the aged, but the process may be amazingly latent in comparison with that in younger years. Ulcer becomes increasingly rare with advancing years. Acute appendicitis is now believed to be more common than was formerly thought but, because of its usual mild onset, is much more dangerous and difficult to diagnose than in youth. Tuberculosis is not as rare as might be anticipated. Both the lobal and bronchial forms of pneumonia are common. Here too the symptoms may be so mild that diagnosis is often difficult. Most acute infections are less common and when present are likely to be symptomatically milder, although more fatal and productive of serious complications.

Perhaps the degenerative changes rather than the diseases proper identify old age most sharply. As we grow older, according to Horn, there is a decrease of water and an increase in calcium content in the tissues, with consequent loss of resilience. The vasomotor upsets of the menopause frequently carry over into the years of senescence. In such instances irritability, impatience, inability to relax and insomnia are frequent. The progressive hypertrophy of the prostate in advancing years is a common source of progressive decline. The obstruction that it produces frequently causes back pressure on the kidneys, and the resultant nitrogen retention may gradually affect the whole organism. Loss of weight, diminishing appetite, lack of gastric secretion and diverticulosis of the esophagus or bowel may perhaps all be considered incident to senescent degeneration.

Sclerosis of the blood vessels is well nigh universal in this age group but makes its appearance at different ages and progresses with varying rates of speed. The cerebral circulation and the nervous system are often involved early. An early loss of memory is not, however, necessarily on a circulatory basis, since sometimes cerebral deterioration is not found in even far advanced arteriosclerosis of the brain.

The wise physician must be on the alert to recognize acute preventable diseases in a far less obvious form than in younger persons. He must recognize also that there is often less which can be done for these diseases. The average elderly patient, according to Horn, is not tolerant of extended diagnostic studies and is often merely forced into it by the urgings of overanxious relatives. Worcester⁴ emphasizes this point in an exceptionally able and unusual discussion of the subject. "The relief and comfort of our aged patients

³ Pepper O. H. *Notes in the Field of Geriatrics*. *VI Clin. North America* 20: 127 (July) 1936.

⁴ Worcester Alfred. *The Care of the Aged, the Dying and the Dead*. Baltimore: Charles C. Thomas, 1935.

should be our aim, rather than the prolongation of their lives. But this is hardly a true distinction, for the relief and comfort given to an aged patient often effect the prolongation of life if only by restoring the willingness to live." The restriction of food and of fluids seems to be desirable in the prolongation of life and healthfulness of old age. It is, however, too common for elderly persons to reduce their diet by limiting food essentials either because of some idea of their own or because of advice from a well meaning but ill advised physician. Few apparently drink any milk at all and deficiency of vitamins may be more common in old age than is often recognized. Glandular deficiencies are probably an integral part of senescence, but thyroid and insulin when indicated should be administered cautiously. Sedative drugs and morphine act quite differently in older persons, and overdosage and addiction are dangerously easy. Rest is important, but the frequent neglect of exercise should be remedied. The problem of laxatives is often difficult but must be solved for each patient individually. Finally, as Worcester has emphasized, the psychologic approach to older patients is of the greatest importance. They are frequently dependent on the physician not so often for drugs or directions as for the human support which perhaps means more in advanced years than at any other time. It is desirable to shun the impossible task of rejuvenation, to preserve the habitual pleasures and to adjust professional visits to the psychologic necessity of the patient rather than to the purely physical and that may be rendered.

Current Comment

RETENTION AND ELIMINATION OF SELENIUM

As already pointed out in *THE JOURNAL*¹ the poisonous character of the forage crops and grains grown in certain of the North Central and Western states in this country is due to the presence of compounds of selenium in these feeds. Many people living in these regions excreted appreciable amounts of selenium in the urine and showed symptoms of chronic selenium poisoning. Of considerable interest therefore are the recent studies from the National Institute of Health on the distribution of selenium in tissues in chronic poisoning and its elimination from the body. Sodium selenite was administered subcutaneously or by mouth to cats for from fifteen to 188 days and in dosages representing from 0.02 to 0.25 mg. of selenium per kilogram of body weight. A large part of the substance (from 50 to 80 per cent) was excreted in the urine, a greater proportion when the selenite was given subcutaneously than when given by mouth. The concentration in the urine was closely parallel to the level of

intake. Much less of the selenium administered was present in the feces, particularly when the substance was given subcutaneously. After chronic poisoning the liver, spleen, kidney and pancreas contained the greatest concentrations of selenium. Although the blood contained relatively small amounts, more was found in the red cells than in the plasma. In another study² of the toxicity of selenium in rats, cats and rabbits it was observed that whereas its continued administration was cumulative in its effects, much of it was susceptible to detoxication. Furthermore there was no evidence of an acquired tolerance to this element. After some 170 days of administration of sodium selenite the urinary excretion in four animals was from 190 to 252 micrograms per hundred cubic centimeters. The selenite was then discontinued, within two weeks there was a sharp drop in the selenium excretion and in a month only from 3 to 19 micrograms was present in the urine. It is apparent that the elimination from the body is rapid though traces persist notably in the liver, for a long time. Though there is no assurance that the greater portion of even any of the selenium ingested by man and animals on seleniferous soils is in inorganic form and is therefore as toxic as sodium selenite the foregoing studies will serve as an important guide in estimating the health hazard to those who live in regions where selenium occurs in the soil, water and food plants.

THE PATIENT HIMSELF

The phenomenal advances of medical science have so largely engrossed the attention of students and teachers of medicine that our schools are charged frequently with failure to teach the embryo physician that his patients are human beings and that he must treat individuals not mere manifestations of a disease. One of our leading universities has made a definite effort to counteract this tendency and their experience of seven years seems to have more than justified the undertaking. Elsewhere in this issue Bailey and Weiskotten¹ describe the procedure employed at Syracuse to demonstrate to undergraduate students the importance of considering the personality of the patient and all the factors environmental and otherwise, which, impinging on him inevitably influence and perhaps greatly modify his reaction to disease. Especially wholesome in the Syracuse plan is the stress on having the student himself investigate the social, economic, religious or industrial relationships of his patient instead of depending on the second hand information relayed by a social worker. On the doctor is laid the responsibility for understanding all the adjustments that may be needed in order to give to the patient the best possible chance of recovery. An index of the success of the method may be found in the work recently published by a Syracuse graduate, "Disease and the Man" which is briefly reviewed in this issue of *THE JOURNAL*.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct 13, 1937, and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p m eastern standard time, 1 p m central standard time, 12 o'clock noon mountain standard time and 11 a m Pacific standard time.

The dates and topics of the broadcasts for the coming month are as follows:

Diet

December 29—Dietary Fads: facts vs fallacies in relation to prevalent false notions on diet.

Contagious Diseases

January 5—Sneezes and Snuffles: cause, spread, prevention of colds, pneumonia and influenza, importance of early medical care.

January 12—Scarlet Fever, Measles and Whooping Cough: modern attitudes toward these diseases, their prevention by community cooperation.

January 19—Smallpox and Diphtheria: unnecessary diseases, preventable by immunization of infants.

The stations on the Red network are privileged to broadcast the program but, since it is a noncommercial program, they are not obliged to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal—Ernest O Lawrence, PhD professor of physics and head of the radiation laboratory, University of California Berkeley, was recently awarded the Hughes Medal of the Royal Society, London, for his work on the development of the cyclotron and its application to investigation of nuclear disintegration, according to *Science*.—Dr Solomon Strouse, formerly of Chicago, has been appointed associate clinical professor of medicine at the University of Southern California Medical School, Los Angeles.

Residency in Physical Therapy—A residency in physical therapy has been established at the Los Angeles County General Hospital. The resident must be a graduate of an approved medical school of recognized standing, must have completed satisfactorily one year's rotating internship in an approved hospital and possess, or be able to secure promptly, a physician and surgeons certificate to practice in California. His experience must include one year's recent full time experience in the administration of physical therapy in an approved hospital some of which must have been in a supervisory capacity. The Los Angeles County Civil Service Commission will give additional information concerning the residency.

Midwinter Course in Ophthalmology—The seventh midwinter course of the Research Study Club of Los Angeles, January 17-28, will include sixteen lectures on ocular muscles by Dr Alfred Bielschowsky, professor of ophthalmology, Dartmouth Medical School, Hanover, N H. Other lecturers will include Drs Edward Jackson, Denver; John O McReynolds, Dallas, Texas; and Frederick Jobe, BS, of the scientific bureau of Bausch and Lomb, Rochester, N Y. Work on the ear, nose and throat will be covered by Drs Arthur

W Proetz, St Louis; Grant L Selfridge, San Francisco; Walter P Covell, San Francisco; Simon Jesberg, Los Angeles; Louis K Guggenheim, St Louis; John F Barnhill, Miami Beach, Fla; and Vern O Knudsen, PhD, Los Angeles. Applications to take the course should be made to Dr Donald S Dryer, secretary, 2007 Wilshire Boulevard, Los Angeles. The fee is \$50. Dr Barnhill's course in dissection and cadaver surgery of the head and neck will begin January 10. It is limited to fifty persons and the fee is \$100.

COLORADO

Appointments to State Board of Health—Dr James S Cullyford has been appointed director of the newly created division of rural health work and epidemiology of the Colorado State Board of Health. Dr Cullyford graduated at the University of Colorado School of Medicine, Denver, in 1933 and received his certificate in public health from the University of Minnesota School of Public Health in June 1937. Frank S Morrison, LL B, has been appointed director of vital statistics of the state board. He recently completed a course on general statistics at the Johns Hopkins School of Hygiene and Public Health, Baltimore.

IDAHO

State Board Abandons Reciprocity Relations—At its meeting in Boise, October 5-6, the Idaho Medical Examining Board passed a resolution canceling all reciprocity provisions in the granting of licenses for the practice of medicine and surgery in Idaho and provided that in the future all applicants will be examined by the Idaho board. It was provided further that an applicant for license will be entitled to a credit of 0.5 per cent for each year of practice obtained prior to his application for license in Idaho, not including years spent in hospital internship or residencies.

ILLINOIS

New Health District—The public health units in Champaign and Urbana have been combined in a new health district replacing the former separate health activities in the two townships. Dr G Howard Gowen has resigned as assistant to the chief division of communicable diseases, state department of health, Springfield, to direct the new unit, effective December 6.

Society News—Dr Lee C Gatewood, Chicago, discussed 'Gastric and Duodenal Ulcer' before the Will-Grundy County Medical Society at Joliet November 24. At a meeting of the medical societies of Lee and Whiteside counties in Sterling, November 18, Drs Philip H Smith, Evanston, Ill, and Raymond F Grisson, Chicago, spoke on "Contraindication of Cesarean Section: Prevention and Treatment of Abortion" and on "Treatment of Infectious Diseases" respectively.

The Du Page County Medical Society was addressed in Elmhurst November 17 by Drs Roland P Mackay on "Treatment of Neurosyphilis" and Eric Oldberg on "Surgical Treatment of the Complications of Neurosyphilis", both are of Chicago. Dr Walter H Baer, Peoria, discussed "Shock Therapy of Schizophrenia: The Use of Insulin and Metrazol" before the Sangamon County Medical Society in Springfield December 2.

Chicago

Medical and Dental Laboratory Building Completed—The new building containing the medical and dental laboratories of the University of Illinois has been completed and occupied. The new unit is of red brick, collegiate gothic and cost \$1,550,000. Seven of the fifteen floors are devoted to the medical facilities and the rest to the dental clinics. The building connects through corridors with a similar unit entirely occupied by the medical school and with the Illinois Research and Educational Hospital, which supplies the patients and nurses. New equipment includes a biplane fluoroscope. A cancer clinic is to be started in lead lined rooms in the basement with \$300,000 already appropriated for radium and equipment. It is reported Dr David J Davis is dean of the medical school, Frederick B Noves, DDS, of the dental school and Dr Major H Worthington is in charge of the research and educational hospital.

INDIANA

Personal—Dr George E Denny, Madison, has been appointed medical superintendent of the Muscatatuck Colony for feebleminded at Butlerville. Dr Herman G Morgan has completed twenty-five years' service as secretary of the Indianapolis board of health. Dr and Mrs Walter R Hutcheson, Greencastle, have given a new \$30,000 nurses' home to the Putnam County Hospital.

announced. It is planned to use the money as the nucleus of an endowment fund to establish a self-sustaining cancer service for indigent patients at the hospital, it was said.

SOUTH CAROLINA

Personal—Dr Andrew A Walden, North Augusta, was chosen as the outstanding citizen of the town by the local post of the American Legion and received a bronze plaque at ceremonies on Armistice Day—Dr John F Busch has resigned as superintendent of the Greenville County Sanatorium, Greenville, to join the staff of the Georgia State Board of Health, it is reported.

TENNESSEE

Society News—Dr Eugene Orr, Nashville, addressed the Davidson County Medical Society, Nashville, October 26, on "Pseudosinusitis"—Speakers at the meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society in Savannah October 26 were Memphis physicians Drs Robert Lyle Motley, on "Treatment of Congestive Heart Failure and Edema in General", Lucius C Sanders, "Thyroid Disease, with Special Reference to Its Effect on the Heart", Mike W Holehan, "Etiology, Pathology and Rational Treatment for Hemorrhoids" and Charles W Ingle, "Treatment of Malignant Tumors of the Breast"—Dr Alvin J Weber Jr, Knoxville, addressed the Knox County Medical Society, Knoxville, October 26, on "Infirmities of the Aged"—Drs Homer D Hickey and John W Hocker, Chattanooga, addressed the Hamilton County Medical Society, Chattanooga, November 11, on "Gall-bladder Surgery" and "Diphtheria Its Diagnosis and Management" respectively.

VIRGINIA

Graduate Course at the University—The fourth graduate course in ophthalmology and otolaryngology was held at the University of Virginia Department of Medicine and the University Hospital, December 14-17. The following were instructors: Drs Francis H Adler, Oscar V Batson, Philadelphia, Bernard Samuels, James W White, Frederick M Law and Robert E Buckley, New York, Vincent W Archer, Charlottesville, and Stacy R Guild, Ph D, Baltimore, and Mr Edgar B Burchell, New York.

Society News—A symposium on diseases of the respiratory tract was presented at a meeting of the South Piedmont Medical Society, November 16, by Drs Edward B Robertson, Danville, James Morrison, Lynchburg, and Rawley H Fuller, South Boston—Dr Horton R Casparis, Nashville, Tenn, addressed the Norfolk County Medical Society recently on "Medical Aspects of Child Training"—Drs Francis Bayard Carter and Wilburt C Davison, Durham, N C, addressed the Danville-Pittsylvania Academy of Medicine at a recent meeting on "Toxemias of Pregnancy" and "Sulfamidamide Therapy" respectively—At the quarterly meeting of the Mid-Tidewater Medical Society at Millers Tavern, October 26, the speakers were Drs Harry A Tabb, Gloucester, on "Practical Methods of Infant Feeding", Malcolm H Harris, West Point, "Treatment of Burns in the Home", and Clarence Campbell Sparta, "Eclampsia"—Dr John T Hundley Jr, Lynchburg, addressed the Lynchburg Academy of Medicine, November 1, on "Clinical Significance of Erythrocyte Sedimentation Test"—Dr Howard R Masters, Richmond, addressed the Fredericksburg Medical Society at its November meeting on mental hygiene.

WISCONSIN

Personal—Dr Archibald D Campbell, Richland Center, was honored with a testimonial dinner, October 21, by physicians of the community and the surrounding territory. Dr Campbell is 72 years old and graduated from the Louisville Medical College in 1896—The house of delegates of the State Medical Society of Wisconsin at its recent annual meeting decided to send the executive secretary of the society, Mr J George Crownhart, to Europe to make a critical first-hand study of sickness care operating under control of governments in various countries.

District Meetings—Drs Joseph E Schaefer and Edward H Hatton, Chicago, were the guest speakers at a joint meeting of the fifth councilor district of the State Medical Society of Wisconsin and the eighth dental councilor district, November 18. Dr Marcos Fernan-Nunez, Milwaukee, spoke after dinner on "Spanish Medicine and the Spanish Revolution"—The autumn meeting of the ninth councilor district was held at Marshfield November 3 with the following speakers: Drs Leland C Pomainville, Wisconsin Rapids, on "Chest Injuries",

Clifford F Broderick, Nekeosa, "Recent Advances in the Therapy of Arterial Hypertension", Karl H Doege and Robert S Baldwin, Marshfield, "Clinical Cases of Nephritis", Winchell McK Craig, Rochester, Minn, "Surgical Treatment of Hypertension" and "Neurosurgical Aspects of Head Injuries," and Carl W Apfelbach, Chicago, "The Importance of Pathologic Examinations."

Society News—Dr Walter P Blount, Milwaukee addressed the Brown-Kewaunee-Door County Medical Society, Green Bay, November 9, on "Fractures in Children"—At the annual meeting of the Grant County Medical Society in Lancaster in October the speakers were Drs Arnold S Jackson, Madison, on "Errors in the Diagnosis and Treatment of Hyperthyroidism", Roscoe L McIntosh, Madison, "Pyogenic Dermatoses", Lyman A Copps, Marshfield, "Indications for Bronchoscopy" and Alexander R MacLean, Rochester, Minn, "Infantile Paralysis"—Dr Matthew N Federspiel, Milwaukee addressed the Racine County Medical Society, Racine, November 3, on "Maxillofacial Injuries"—Dr Milton Trautmann of the state board of health, Madison, discussed diagnosis and treatment of syphilis at a meeting of the Waupaca County Medical Society, New London, November 17—Dr John H J Upham, Columbus, Ohio, President of the American Medical Association, and Clarence A Dykstra, Litt D, president of the University of Wisconsin, Madison, were speakers at the annual dinner of the Medical Society of Milwaukee County December 9 in Milwaukee.

GENERAL

Changes in Status of Licensure—The following action of the Florida State Board of Medical Examiners has been reported:

Dr Lemuel A Carter Bunnell Fla license restored.

The Minnesota State Board of Medical Examiners reports the following action:

Dr John Lynn Erickson Canby license suspended November 12 for two years for conduct unbecoming a person licensed to practice medicine and detrimental to the best interests of the public.

The Wisconsin state board of medical examiners reported the following action taken at a meeting October 14:

License of Dr Elgie Krut Lancaster revoked on the basis of a court record of his conviction and sentence for performing an illegal operation.

Fraudulent Salesman—The National Publishers Association, Inc, reports the activities of a man who has been soliciting magazine subscriptions among physicians, giving the name of a fictitious company as the distributor. He has sold the magazines at low rates, pocketed the collections and made no report to the publishers. He is said to use a printed form carrying the name Frank Crowell, 55 West Forty-Second Street, New York, N Y. There is no such person at the address given and mail so addressed will be returned marked "Unknown". The man uses the names L Hordes, George Cowan, J Stern and Jack Stern. The following description is given: age 30 to 32, height 5 feet 8 or 10 inches, weight 170, dark hair, dark complexion, thick lips, loud speech, rapid actions, displays nervousness, two teeth missing in front of mouth, lower teeth protrude slightly past uppers, slightly protruding lower jaw, shabbily dressed. The publishers association asks any person solicited by this man to notify the police and wire the association collect. The address is 232 Madison Avenue, New York, N Y.

Impostor Defrauds Pathologists—Physicians in Louisville, Ky, and Topeka, Kan, have recently reported activities of a man who poses as Dr Eustace L Benjamin, associate professor of pathology, Northwestern University Medical School, Chicago, and who thereby induces physicians to endorse checks subsequently proved to be worthless. Several other pathologists recently reported that they had been approached by this man, who has also used the names of Dr Emmerich von Haam, Columbus, Ohio, and Dr James P Simonds, Chicago (THE JOURNAL, November 6, page 1552). The real Dr Benjamin stated at that time that he cashed a check during the past winter for this man, who said then he was a pathologist from Mercy Hospital, Canton, Ohio. Checks for amounts ranging from \$10 to \$100 have been cashed for him by pathologists in several laboratories. The impostor is said to be about 40 years old, of average size, with hair tinged with gray. His neck is short and thick, his face is round and his eyes bulge somewhat. He is familiar with terminology and has a fair knowledge of laboratory methods, according to the reports.

Appendicitis Mortality in 1936—Statistics from 183 American cities show that there were 144 deaths of appendicitis per hundred thousand of population during 1936, a slight reduction from the rate of 1935, which was 147. The lowest rate on record is 13, which occurred in 1918. Rates for individual

cities ranged from no deaths in Cicero, Ill., and Orange, N. J., to 877 in Shreveport, La. No satisfactory explanation of the great variation can be advanced without a thorough study of local factors, according to Frederick L. Hoffman, LL.D., consulting statistician of the Biochemical Research Foundation of the Franklin Institute, Philadelphia, who made the tabulation. The ten cities with the highest rates are: Shreveport, 877; Wilkes Barre, Pa., 365; Sioux City, Iowa, 353; Passaic, N. J., 351; Oak Park, Ill., 341; Camden, N. J., 316; Nashville, Tenn., 309; Knoxville, Tenn., 301; Salt Lake City, Utah, 301; and Memphis, Tenn., 294. These rates are affected by local hospital facilities, the report said. The ten cities with the lowest rates, other than the two with no deaths, are: Newton, Mass., 14; Covington, Ky., 15; Union City, N. J., 16; Bethlehem, Pa., 17; Gary, Ind., 27; San Jose, Calif., 29; Newport, R. I., 33; Yonkers, N. Y., 34; and Fresno, Calif., 35. Mortality in the five largest cities was as follows: New York, 126; Chicago, 13; Philadelphia, 11; Detroit, 16; and Los Angeles, 151. Dr. Hoffman also analyzed the figures geographically and by age and sex. According to his table the rate was highest in the western mountain region, 25 per hundred thousand, a fact that might be explained by inaccessibility of medical and surgical aid, he pointed out. The rate for white men reached a maximum of 244 for the age group 75 to 79, while for white women the maximum rate was 168 for the age group 60 to 64.

General Meeting of Bacteriologists' Society—The thirty-ninth general meeting of the Society of American Bacteriologists will be held in Washington, D. C., December 28-30, at the Mayflower Hotel under the presidency of James M. Sherman, Ph.D., Cornell University, Ithaca, N. Y. Among speakers who will address the section of medical bacteriology, immunology and comparative pathology will be:

Michael Heidelberger, Ph.D., New York: Antigenicity with Special Reference to Infectious Agents.
Dr. Edwin W. Schultz, Stanford University, California: Antigenic Properties of Poliomyelitis Virus.
Dr. Harry S. Eagle, Baltimore: Effects of Formaldehyde on Horse Antipneumococcus Serum and Diphtheria Antitoxin and Their Significance for the Theory of Antigen Antibody Aggregation.
Dr. Earl B. McKinley, Washington, D. C.: Intradermal Tests in Leprosy with Antigens of Acid-fast Bacteria.
Walter J. Nungester, Sc.D., and Roy G. Klepser, Ann Arbor, Mich.: A Possible Mechanism of Lowered Resistance to Pneumonia.
Dr. Chester S. Keefer, Boston: Bacteriolytic in Gonococcal Arthritis.
Dr. Perrin H. Long and Eleanor A. Bliss, Sc.D., Baltimore: Experimental and Clinical Observations upon Chemotherapy in Gonococcal Infections.
Dr. Ralph R. Mellon and Lawrence E. Shinn, Pittsburgh: Limiting Factors of Sulfanilamide's Action and the Phenomenon of Potentiation.
Francis B. Gordon, Ph.D., and Edwin H. Lennette, Ph.D., Chicago: The Blood Stream in Experimental Poliomyelitis.
Dr. Albert B. Sabin and Peter K. Olitsky, New York: Mode of Action of Zinc Sulfate Spray in Preventing Infection with Nasally Instilled Poliomyelitis Virus.
Jean Broadhurst, Ph.D., and Gladys Cameron, New York: Virus Forins Present in Scarlet Fever.

FOREIGN

Personal—Sir Henry H. Dale, director of the National Institute for Medical Research, London, has received the Copley Medal of the Royal Society of England in recognition of his "important contributions to pharmacology, particularly to the pharmacology of muscle and neuromuscular transmission." In 1933 Sir Henry delivered the Dohme Lectures at Johns Hopkins University School of Medicine, Baltimore.—Major-General William P. McArthur has been selected to succeed Lieutenant-General Sir James A. Hartigan as director-general of Army Medical Services when the latter completes his tenure of office March 1, 1938.

Government Services

Dr Morgan Named Regional Consultant

Dr. Thomas E. Morgan, health officer of Pinellas County, Fla., with headquarters in Clearwater, has been appointed regional medical consultant to the Children's Bureau of the U. S. Department of Labor for the southeastern district. Dr. Morgan will have his headquarters in Washington, D. C. The southeastern district includes the District of Columbia, Delaware, Virginia, West Virginia, Georgia, Florida, North Carolina and South Carolina. Dr. Morgan, who is 37 years of age, graduated at the University of Georgia School of Medicine in 1925. For several years he was associated with the state board of health in Jacksonville and in June 1936 was appointed director of the newly created health unit in Pinellas County.

What Is Wrong with the British Diet?

A former chief medical officer of the Ministry of Health, Sir George Newman, said that the British people were better fed than at any period of their history. That appears to be true, but, in the crusade now going on to improve the health of the people, attention is concentrated on exercise and nutrition, and alleged malnutrition has been used as a political weapon in attacking the government. No doubt there is room for improvement, but whatever defects exist in the British diet are due more to unwise spending than to want of means. In an article in the *Times*, the dietitian Sir Edward Mellanby, says that we are at the beginning of a great movement to prevent ill health and disease. In the British diet the bulk of the foods—cereals, pork, poultry, white fish, vegetable oils, sugar and jam—are deficient in mineral elements, especially calcium, and in most of the vitamins. These deficiencies are not made good by the enormous consumption of the national beverages—tea, coffee, beer and alcohol. But there are "protective foods" which are rich in these essential substances—milk and other dairy products, eggs, green vegetables, liver and other glandular organs, fat fish such as herring, mackerel and salmon, fish oils and fruit. If a sufficiency of these protective foods is not eaten, poor physical development and certain forms of ill health follow. Our diet should include a much larger amount of these and not be overweighted, as it is, with energy-giving foods. Unfortunately the protective foods are relatively expensive as compared with cereals, so that the poorer the people the greater the proportion of nonprotective foods eaten. For the young and for adolescents the problem is much more important than for adults. This explains, Mellanby thinks, the many years that have elapsed between the discoveries of science and the present public interest in proper feeding. If a dietetic cure could have been found for cancer or chronic rheumatism of the adult, it would undoubtedly have been seized on with avidity. But our future adults should be considered. If we want British athletes to carry off the world's laurels, we must see that they grow from birth under conditions of perfect nutrition. There is less mystery in the remarkable athletic abilities of the Finns when it is remembered that their daily milk consumption is three per head that of the British.

The habit of giving children tea is wrong. Their normal drink should be milk containing from 3 to 3.5 per cent of fat, not rich in cream, which often upsets them. Mothers would be saved much trouble and anxiety if they gave their infants, even the breast-fed, a small teaspoonful of cod liver oil daily, from the day of birth. Up to the end of adolescence the daily milk ought not to be less than one pint, and two pints would be better. This supplies the abundance of calcium required for the growth of the bones and teeth. The trouble with adults is that they eat what pleases them. They would be well advised to take a pint of milk daily and to look with favor on eggs, green vegetables and other protective foods. They would then be fitter and the days of chronic ill health would be delayed. For the sedentary well-to-do over 40 milk might well replace two of the three lots of meat indulged in daily. The objection that milk makes people fat holds only when it is taken as an extra; it ought to replace some of the bread, sugar or other energy-bearing foods. In Tristan da Cunha where until lately there was no bread or other cereal and the main food was milk, mutton, fish, eggs and potatoes, there was no rheumatism or arthritis and the teeth were relatively free from caries. In recent years well-meaning people have been sending flour and

sugar to the island and, as might be expected, the first curse of civilized communities, dental caries, is increasing among the children

The Reconditioning of Army Recruits

Until recently, army recruits had come up to prescribed physical standards and, if they did not, were rejected. But in this free country recruiting is purely voluntary and the obtaining of sufficient force for defense in a conscript Europe, armed to the teeth, has become a problem. The army authorities have therefore embarked on the experiment of endeavoring to make fit for the army, by dieting and exercises, men who previously would have been rejected. For the first time in army history a recruits physical development depot has been established. Formerly if a chest failed to fill the tape measurement or a head to touch the height recorder the applicant, perhaps otherwise full of promise, was rejected. Now the men who fall just below the borderline are taken on approval and undergo a course of training to make them fit. While the ranks were short by 10,000 men, 68 per cent of applicants were being turned away for minor disabilities. So far the experiment has been successful and those who appeared to be poor material have been turned into men erect in carriage, well developed and sound in mind and limb. Such defects as slight curvature of the spine, flatfoot and fast heart have yielded to the treatment. Further, the mechanization of the army has allowed differences of standard to be introduced. The first line fighting troops must be physically sound, able to march carrying a pack and able to eat "hard" rations. Men of the "mechanized class" need not be particularly good marchers, but they must qualify as marksmen and occasionally subsist on "hard" rations. Motor drivers normally receive cooked rations and are not called on to march but must have good sight. In recent years out of three men applying for enlistment one was rejected at sight, the second was rejected on physical medical or educational grounds, and the third was accepted.

Suppression of Quackery

The uncontrolled exploitation of all sorts of cure-alls in the newspapers here and the license to advertise claims of miraculous cures, such as sympathicotherapy, the latest form of quackery here, has at last aroused the medical profession to plan a counteroffensive. In the November 21 issue of the *Concours medical*, Dr Lavalee quotes the paragraphs of a bill which Mr. Henri Sellier, who was minister of public health until the resignation of the last cabinet, had planned to have passed by the legislature. In the first section, any one who advertises a drug or method of diagnosis or cure is prohibited from using the word "cure," to publish any testimonial in which a "cure" is described, to add any comments on the medical aspects of any method or drug or to describe the symptoms of the disease which can be relieved. These restrictions are especially applicable to reputed tuberculosis, cancer and venereal or menstrual disturbance "cures." All such infractions are to be penalized. This proposed law was criticized because it left a loophole for quacks who claim to cure hernias, varicose veins, obesity and diseases of the scalp, rheumatism and other conditions, but the ex-minister of public health said that before the bill became a law these forms of quackery could be included.

Unfortunately, this bill was never introduced and the journals are filled with the advertisements of all forms of quackery. One of these, sympathicotherapy, which makes diagnoses by pressure on supposed sympathetic nerve endings in the nasal septum, has a dozen branch offices in Paris and some in every large city of France. Lavalee in his editorial states that as long as no laws exist to suppress quackery the only hope of the profession is to try to enlighten the public by all forms of

propaganda by means of the radio, cinemas and newspapers. The question is Who will pay for such a campaign against quackery, and how much will it accomplish? A certain number of people want to be deceived and will lend an attentive ear to claims of cures which border on the miraculous.

One means of combating this ever increasing wave of quackery would be to have a council on pharmacy and chemistry (like that of the American Medical Association) appointed, to which manufacturers of pharmaceutical specialties, of which there are thousands in France, should submit their preparations voluntarily for the approval of the council. Any one who knows the chaotic state at present of such supervision in France will welcome the plan, but Lavalee says that the task of the council will not be an easy one. It would be ideal to have laws in force which already exist in other countries, that all foods and drugs must receive official approval before being placed on sale.

Social Laws and Hospitalization

At the first French Hospital Congress, held recently in Paris, a paper was read by Dr. Renon of Niort on the effect of assistance and other social laws on hospitalization in France. He emphasized that the old notion that public hospitals receive only those unable to pay no longer holds true for the present state of affairs. The advances made by the medical sciences on the one hand, but more particularly the evolution of the laws of assistance and of social medicine, have transformed the meaning of the term hospitalization. Although the number of persons who have received aid from the state has decreased considerably since 1890, the number of such persons who have been hospitalized has increased by 82 per cent, which means that less and less care is being given at the homes of the indigent. The legislation covering industrial accidents has also greatly added to the number who receive hospital treatment. Those covered by the social insurance law of 1930 are reimbursed for any outlays incidental to illness or confinements. The sums allowed for such care are so small that the majority of the insured find it cheaper to go to public hospitals, where a fixed rate of about \$1.50 a day for the socially insured is less than they would be obliged to spend to be cared for at home or in a private hospital. It must be remembered that the socially insured are not reimbursed in full for their outlays, but only to the extent of 80 per cent of these.

At present, in addition to indigents, the industrially injured and the socially insured, a fourth group of "pay" patients are now received in public hospitals. There has been an increase since 1900 of over 210 per cent in the number of this fourth group who are being hospitalized. The growth of hospital facilities has not kept pace with the number of applicants for hospitalization, being only 76 per cent of what they ought to be. There is a complete lack of coordination between the social role of public hospitals and their technical and judicial organization. By the word judicial is meant that legislators pass all sorts of laws to promote the extension of free medical aid without taking into consideration the necessity of providing corresponding hospitalization facilities, particularly in the case of pulmonary tuberculosis. The only relief from the present situation is to permit all private hospitals to receive the socially insured at a fixed rate instead of limiting this privilege to those who have made contracts with the caisses, or social insurance disbursing offices. If the insured do not wish to enter private hospitals, provision should be made, at least in public institutions, for receiving the socially insured in small wards to be reserved for pay patients and every qualified physician should be allowed to take care of such patients, instead of limiting the privilege to the regular staffs of the public hospitals. In order to avoid the resulting confusion only such physicians as have passed a special examination shall be allowed to treat private patients in public hospitals and receive remuneration from the patients. The latter privilege is also to be given members of

the regular staff who have occasion to treat such patients. This would put a stop to the present system of having the staff treat pay patients in public hospitals without any recompense.

French Ophthalmologic Congress

The first meeting of the French Ophthalmologic Congress was held June 28-30 in Paris. A paper on optochiasmatic arachnoiditis was read by Drs. Bollacq, David and Puech, based on 129 observations, of which sixty three were found in the literature and the others from the neurosurgical service of La Pitié Hospital. An exploration of the region of the optic chiasm had been carried out in all of the 129 cases. Clinically, they are characterized by varied visual disturbances and pathologically by changes which it has been possible to study only as the result of operative intervention. The extra-ocular clinical forms are less important than the purely ocular ones. The latter can be placed in three groups: (1) the macular neuritis syndrome, characterized by a diminution of vision, a central scotoma and papillary changes, of which atrophy with poorly demarcated edges is the most typical, (2) a chiasmatic syndrome with decreased visual acuity, atypical and asymmetrical changes in the temporal field and by papillary atrophy, and (3) the simple atrophy syndrome of the optic nerve with concentric narrowing of the visual field. Certain forms with lateral hemianopia, with decrease on the nasal or horizontal side of the visual field, are less often seen.

The diagnosis is difficult because of the protean character of the symptoms and the fact that none are characteristic, being found in other conditions. Ventriculography is the most important method of differential diagnosis from tumors of the hypophysis.

A description was given of the technique of transfrontal exploration, which has a low mortality. The best results followed operation in early cases in which (a) visual acuity had not been altered materially in a peripheral direction and especially centrally, and (b) when a not too accentuated optic atrophy was present.

In the discussion, François of Belgium reported the experience of a patient who showed a bilateral papillary stasis with rapid diminution of vision after eighteen months' treatment for syphilis. The neurologic examination was negative but there were typical cytologic and chemical changes in the spinal fluid. Energetic antisiphilitic treatment did not prevent blindness, and a decompression was of no benefit. An exploratory endocranial exploration revealed an optochiasmatic arachnoiditis and was followed by a restoration of one-fifth vision to the left eye, a complete atrophy persisted on the right side. Three months later, pyretotherapy was used and resulted in a restoration of vision in the right eye of about two thirds and an almost normal visual field, which has continued for more than a year.

Recurrent Hematemesis with Splenomegaly

At the October 15 meeting of the Société médicale des hôpitaux a case was reported by Milhit and his associates of recurrent gastric hemorrhages in a boy, aged 10 years, with greatly enlarged spleen. Microscopic examination of the spleen after its removal revealed a thrombosis of the splenic vein of long duration, as well as changes in the reticulo endothelial structure. The rapid decrease in size of the spleen after a hemorrhage or the use of epinephrine shows that the splenomegaly is essentially the result of stasis. At operation an extensive collateral circulation is found already developed in the gastrosplenic and phrenosplenic ligaments. Removal of the spleen decreases the likelihood of formation of gastric varicosities, the rupture of which is followed by severe hemorrhages.

Grenet stated that this syndrome is not rare in children and that he had observed recurrence of hematemesis in spite of splenectomy. The latter should not be done if there was marked diminution in size of the spleen after administration of epinephrine.

Tiessinger had seen cases of splenomegaly with and without phlebitis and thrombosis. The occurrence of phlebitis and thrombosis of the splenic vein did not bear any etiologic relation. A primary splenothrombosis is rare. No reliance is to be placed on contraction of the spleen following the use of epinephrine.

Milian stressed the syphilitic origin of many cases and said that one should not be satisfied unless this treatment had been given a long trial. Tzanck had seen cases in which syphilis existed but said that antisiphilitic treatment had not been followed by any improvement. Chevallier agreed with Milian that syphilis plays an important part in the etiology. Typical cases of splenomegaly of the Banti type are encountered in which hematemesis was never reported yet at necropsy submucous gastric hematomas are found. The hematemesis is often due to lesions of infectious character involving the spleen, liver, stomach and radicles of the portal vein. The process may begin in the spleen or the liver. In Banti's disease with thrombosis of the portal vein and without gastric hemorrhages, splenectomy gives excellent results but they are less satisfactory when hematemesis exists. Even so, splenectomy should be given a trial in spite of occasional reports of postoperative death from gastro intestinal hemorrhage.

Nov. 8, 1937

Congress of German Neurologists and Psychiatrists

A joint congress of German neurologists and psychiatrists was held recently. The first topic for discussion was "Brain Tumors." Tonnis contrasted German and foreign data on brain surgery and pointed out the great advances that have been made in diagnosis and therapy. And yet often a diagnosis of brain tumor is not confirmed by operation. Epilepsy was next discussed. On the basis of the German eugenic laws, Pohlisch feels that the term "epilepsy" should be restricted to the hereditary disease. Phenobarbital should be prescribed only in small doses, larger doses produce an exacerbation of the epilepsy. It was the consensus with regard to the metrazol test for suspected epilepsy that in view of the nonspecific character of the induced attacks the drug should be contraindicated as a diagnostic aid.

Another principal theme was "The Use of Tests in Psychotherapy and Vocational Guidance." Enke said that most psychiatric tests may well be rejected, as they are unable to establish irrationality of the human mind. He referred to Kraepelin and his school, who elaborated the technique of mental tests. Yet if any test elucidates even a few details of the pathologic processes, it should not be rejected. The mental test may be of immediate utility within the general scheme of examination but certainly not for itself alone. Special training is necessary for the application of such tests, above all, the observations must be studied in relation to the constitutional type. Of particular importance is the Rorschach test, which helps to establish not only the working capacity but the intellectual possibilities as well. Jung's association test is too little used, it facilitates diagnosis and shortens the course of treatment. Graf spoke on the use of tests in vocational guidance. He emphasized that a test does not guarantee that the subject who shows himself experimentally qualified for a certain occupation will, in fact, be contented in it. Graf advocates a new orientation of psychology as applied to vocational guidance, the important thing is not what the person is capable of doing but what he wishes to do. The speaker referred to the significance of constitutional type psychology for vocational guidance and to the difficulties encountered in this direction, for instance, the question of how far the biologic type permits itself to be determined with certainty. Lottig discussed the value of mental tests for aviators. He said that one cannot establish all pertinent facts by tests and

that the most accurate criterion is still provided by a record of the person's achievements, by an examination of his life history.

Insulin and metrazol therapy of schizophrenia was the final theme discussed. Koppers considers that insulin shock treatment eclipses all other procedures. According to his observations only about 20 per cent of schizophrenic psychoses remain uninfluenced by insulin. There are no accidents worthy of mention if the procedure is skilfully performed. The speaker pleads for its general introduction. In the general discussion, combined insulin-metrazol therapy was rejected, the insulin therapy was almost unanimously conceded superiority. Remissions following the use of insulin were also much better than following the use of metrazol. The opposition which the utilization of insulin therapy for schizophrenia still encounters should be combated.

The German Society of Pathology

A well attended convention of the German Society of Pathology was held in September at Frankfurt-on-the-Main under the chairmanship of Beitzke of Graz. The opening theme was "Allergic Manifestations in Tissue." Professor Berger, Graz internist, differentiated allergic immunity, allergic disease and allergic reactions to vitropression. An identical reaction may be produced by wholly disparate etiologic factors: hormone, chemical, thermic, neurogenic, psychic. Schmidt of Marburg spoke on the pathogenesis of allergies. He dealt at some length with anaphylaxis and serum sickness as well as with the Sanarelli-Schwartzman phenomena. Kalbfleisch of Frankfurt-on-the-Main discussed the morphology of allergic manifestations, which he relates particularly to rheumatism, scarlatina and periarteritis. Many genuinely allergic manifestations are not macroscopically discernible, often it is not possible morphologically to demonstrate the nature of a process, namely, whether it is of allergic or of other origin.

Dietrich of Tübingen stressed the significance of allergic vascular reactions for the problem of thrombosis. Watjen of Halle discussed the question: Is there an allergic basis for the central lobular necroses of the liver frequently observed in infections, as well as in the presence of congestions, metabolic disturbances and carcinoma? The consensus among the delegates seemed to be that there is no such thing as a true morphologically specific allergic reaction and that, for example, the much discussed fibrinoid degeneration and swelling of the connective tissues may also appear in other than allergic processes. Therefore, between "simple" and allergic inflammation there exist only differences in intensity.

The main theme on the second day of the congress was "Occupational Lesions and Cancer." Staemmler of Breslau referred to the inaccuracy of statistics for conclusions relative to the incidence and seat of cancer. K. H. Bauer, Breslau surgeon, said that according to his own observations a cancerogenic substance (benzopyrene) can also act as a therapeutic agent (in skin cancer).

It was agreed in the general discussion that the influence of silicosis on the pathogenesis of pulmonary cancer should be rejected.

Erroneous Diagnoses in Poliomyelitis

Professor Opitz, director of a municipal children's hospital in Berlin, mentions the frequency with which cases of poliomyelitis are falsely diagnosed. Of fifty-four children affected with poliomyelitis, the cases of only thirty-three were correctly diagnosed at the time of admittance. It is sometimes impossible to establish the diagnosis while the disease is in its preparalytic stage. It should be emphasized, however, that in late summer poliomyelitis ought to be considered if an ailing child presents catarrhal manifestations in the upper respiratory tract, mild conjunctivitis, fever and perspiration. If in addition the patient complains of headache and backache, influenza also may be suspected. However, even at this stage sure signs of the true disorder (poliomyelitis) may be present to a certain extent,

for example, stiff neck, Kernig's sign, Brudzinski's sign, hyperesthesia, and diminution of the tendon reflex. These signs should be searched for in any event, since there are abortive cases in which the symptoms develop no further but in which the patient may be a transmitter of infection. Finally, one should keep in mind that sciatica and rheumatism are practically never encountered in children.

The Private Sickness Insurance

In addition to sickness insurance clubs that serve as public insurance underwriters there is in Germany, as elsewhere, an extensive private sickness insurance, a statistical report on which has just been published. On June 30 there were listed as belonging to the group of "private sickness insurance" 615 organizations, namely, 105 larger and 510 smaller sickness insurance clubs. The membership of these clubs on June 30 was 6,981,943 as contrasted with 6,744,460 on Dec. 31, 1936, and 6,264,968 on June 30, 1936. During the first six months of 1937 these clubs received in premiums 152,200,411 marks against 135,000,000 marks in the first half of 1936. The expenditures of the clubs during the first half of 1937 amounted to around 114,000,000 marks against around 99,000,000 marks in the first half of 1936. To still another group, the so called public service sickness insurance, belong thirty-four organizations with a membership of about 1,900,000 insured. The income of these clubs for the first six months of 1937 was 30,000,000 marks, the amount disbursed in payment of claims 25,000,000 marks.

The Alcohol Test in Traffic Accident Cases

In a recent report on the problem of alcoholism and traffic accidents, Dr. Hoffmann of the Sanitary Bureau of the Chief of Police points out how carefully the police proceed with the blood tests and how informative such tests can be. From Oct. 1, 1932 to Dec. 31, 1936, the Prussian police conducted 3,600 blood tests for alcohol. The Widmark method was followed. The published report discloses that the greatest danger of a traffic accident was present on Saturday (20.4 per cent of all accidents occurred on Saturdays) and on Sunday (17.5 per cent of all accidents occurred on Sundays). In 67 per cent of the cases the blood specimen was removed between 7 p. m. and 5 a. m. The greatest number of traffic offenders were from 30 to 34 years of age. Nineteen women, eight of them married, had to be booked for driving while intoxicated.

ITALY

(From Our Regular Correspondent)

Nov. 30, 1937

Synthetic Camphor in Italy

Synthetic camphor was recently placed among the drugs in the Italian official pharmacopeia. The General Department of Public Health sent a circular letter to municipal physicians and pharmacists which contains precise regulations. Jars containing camphor of several varieties in drug stores shall have a label showing, specifically, the quality of camphor contained in it. Pharmacists will fill prescriptions which call for camphor with the pure article unless otherwise specified. Labels on pharmaceutical products containing camphor should denote the nature of the camphor, whether synthetic, natural or Japanese.

Balneario Donated to University

Dr. Eugenio Viviani donated the largest part (six sevenths) of the Salice balneario to the Milan University. The donation includes the balneario, springs, hotels and parks. This is the first time an Italian university was ever presented with a balneario of such great value. The Salice springs have waters containing sulfur, sodium chloride, bromides and iodides. The balneario is to be reorganized. There will be departments for research, teaching and clinical work.

Mortality in Italy

According to statistical data, the mortality in Italy diminished from 1919 to 1936. The annual average for the years 1919 to 1921 was 666,771 for the entire population of the country, which corresponds to 18.3 per thousand of population. From 1931 to 1936 it was 590,291, which corresponds to 14.1 per thousand of population. The annual average stillbirth rate was 4.5 per hundred births from 1919 to 1921. It was 3.4 per hundred from 1931 to 1936. Infant mortality was 129.4 per thousand from 1919 to 1921 and 104.1 from 1931 to 1936.

Society Reunion

The Società di Dermatologia e Sifilografia met recently at Palermo under the chairmanship of Professor Tommasi, the head of the clinic of the Palermo University.

Professor Marchionni spoke on the pathologic chemistry of seborrhea. A seborrheic constitution is necessary for the development of seborrheic eczema. The speaker, in collaboration with Manz, made determinations of the amount of total cholesterol and of the two fractions of cholesterol in chloroformic dialysates of normal skin of patients suffering from seborrhea. The amount of total cholesterol in the superficial layers of the skin of patients suffering from oily seborrhea is increased in comparison to that in the skin of normal persons and the cellular fats contain a large amount of ether. The disorders of the fat metabolism of the skin in seborrhea originate in increased production of cellular fats, which contain a large amount of ether, in the horny layer of the skin. In acne vulgaris the amount of free cholesterol is increased, owing to the accelerated secretion of the sebaceous glands.

Professors Monacelli and Puglisi reported a case of Bowen's disease in which clinical and microscopic studies were performed. A woman, aged 34, suffered from the disease for seven years. The disease involved the vulvar mucosa and coexisted with lichen planus of the mucosae of the mouth and genitalia. Microscopic studies of tissues from the vulvar lesion showed the typical structure of Bowen's disease, which developed from local recurrences of lichen planus.

Professors Bosco and Berna reported studies of the reticulo-endothelial system of lepers which were carried on by Remann and Adler's Congo red test. The granulopoietic power is reduced in lepers. The leprosy nodules do not retain the stain.

Professor Puglisi studied, by means of pharmacodynamic tests, the behavior of the neuro-endocrine apparatus of patients who were suffering from vitiligo and alopecia areata. The two conditions have the same origin. They develop from local vasoconstriction, which is intensified by the presence of hyper-sympathetotonia.

BUDAPEST

Nov. 9, 1937

Centennial Jubilee of the Budapest Royal Medical Society

The Budapest Royal Medical Society celebrated its centennial in the gala hall of the Hungarian Scientific Academy on October 7-10. The ceremony was attended by the prime minister, by the ministers of public instruction and interior, by the mayor of the city and by delegates from foreign medical and scientific societies. The opening address was given by Professor Verebelyi, after which Professor Eiselsberg, Vienna, professor of surgery, lectured on "Dramage and Tamponade." After the lecture, Professor Verebelyi handed to the Austrian guest a silver medal struck off for the occasion. Among the foreign delegates were Professor Kubik on behalf of the German university of Prague, Professor Wadi of the Medical Association of Esthonia, Professor Lubeck of the Medical Chamber of Esthonia, Mustakallio of the Finnish Medical Association, Copeman of the Royal College of Physicians, London, van Kapellen of the Netherlands Medical Society, Kahlmeter of the Swedish Medical Society and Koleszar of

the Transalbanian Museum Association. In the afternoon Professor Staehelin of the Basel (Switzerland) University lectured on "The Change in Diseases in the Latter Decades." From statistics relating to the distribution of various infectious diseases he concludes that phenomena which are strikingly divergent from one another are caused only by external circumstances. On the second day of the meeting a wreath was placed on the statue of Semmelweis and a memorial address was given by Professor Frigyesi of Budapest University. In the afternoon Prof. C. C. Guthrie of the University of Pittsburgh School of Medicine lectured on "Cancer of the Breast and the Results Achieved." In the evening, the city of Budapest entertained at a gala dinner. On the third day Professor Lepine, dean of the Lyons (France) University, read a paper on "Chemical Influences in Neurology." A gala performance of the Budapest Royal Opera and then a banquet by the Hungarian government ended the festivities.

Professor Szent-Gyorgyi

Those who have followed the activity of Professor Szent-Gyorgyi for years were not greatly surprised at his award of the Nobel prize. The young scientist commenced his research on the function of the adrenal gland in a basement laboratory of a university in the Netherlands. After indefatigable work at various other research centers over a period of several years he isolated vitamin C.

Professor Szent-Gyorgyi was born at Budapest, Sept. 15, 1893. His father was the descendant of a Transylvanian nobleman and his mother is the daughter of the late Professor Lenhossék, a physician whose sons are prominent in the Hungarian scientific world. After graduating at Budapest University, Szent-Gyorgyi studied at Bratislava and later at Prague, Berlin and various English and American universities. Since 1930 he has occupied the chair of biochemistry at the Francis Joseph University in Szeged. Eleven years ago while at a university in the Netherlands he conceived the idea that the function of the adrenals must be in connection with the respiration of tissues. From this he went into a study of the respiration of plants, and he discovered in plants a substance which gave rise to peculiar chemical processes. His publications in the medical press by that time had made him well known and the University of Cambridge offered its laboratory for him to use. There he had ample means to pursue his research. He was able to crystallize the mysterious substance from the adrenals and different plants. Then he received an invitation to the United States, where a finely equipped laboratory was placed at his disposal and here he was able to produce 20 Gm. of the problematic substance from the adrenals and plants, yet he still did not know what the substance was, much work was necessary to establish that the 20 Gm. of material which he brought from America to Szeged was vitamin C. Szent-Gyorgyi endeavored to produce from plants a greater quantity of this substance and mere chance played a part. At a certain dinner he did not relish green paprika, which he was accustomed to eat every day before meals, and he put it aside. He recalled that, among the long series of fruits, vegetables and plants which had been investigated in his laboratory in search of Vitamin C, green paprika was not included, so he took the rejected dinner portion to his laboratory and worked the whole night, discovering that green paprika, this popular and cheap vegetable, contains much vitamin C. It was not difficult now to make a large quantity of vitamin C, and shortly he was able to send quantities of it to biochemical laboratories in Europe and the United States as a present. Vitamin C is present in every constituent of the animal cell and it must therefore play a fundamental part in nature.

LACK OF VITAMIN RESULTING FROM ILLNESS

In a recent issue of the *Orthoskepsis* (Postgraduate Medical Education) Szent-Gyorgyi says that the vitamin demand of various organs is not uniform nor is it uniform in one and

the same person under different circumstances. Research has led to the observation that the vitamin C demand of a feverish patient is considerably higher than that of a normal person. Therefore it may come about that, while a patient is on a seemingly satisfactory diet, a lack of vitamin may arise and render his condition worse.

Purpura haemorrhagica of the vascular type may be cured with a certain botanical dye. These dyes, called botanical flavons, have been also named P vitamins. However, the diet of a patient suffering from purpura often does not differ at all from the diet of other persons living in the midst of similar circumstances. The question arises: Why did this one person fall ill with purpura? The answer is: Because his organism had an exaggerated demand, unsatisfied by regular diet, for this substance. Perhaps it is unable to bind the P vitamin taken in with foods. Such an organism can be brought into equilibrium only with a great excess of P vitamin. We encounter cases also in the therapeutic employment of vitamin C that can be explained only on this theory.

JAPAN

(From Our Regular Correspondent)

Oct. 25, 1937

Extensive Outbreak of Dysentery

The number of the cases of dysentery which suddenly broke out on the evening of September 25 in the city of Omuta, with a population of over 110,000, amounted to 11,272 by October 18, with 491 deaths. Seventy per cent of the patients were children. It broke out in the houses where the water is supplied by the city waterworks. As to the cause, it was recently found that in the family of the superintendent of the watershed had been cases of the same disease. There are only forty practitioners in the city, and 114 doctors from medical colleges and hospitals in larger cities have been sent to assist, and two or three doctors from the neighboring towns and cities are being sent every day by turns to help them. Some of the primary school buildings are being used as hospitals. The society of pharmacists of the prefecture voluntarily sends two pharmacists every day to assist in the preparation of medicine. The central government sent health officials, who are assisting. One of the most difficult questions was how to deal with the excrement of each sick family. The farmers became afraid to haul the excrement to their farms and refused to do as before. The city authorities decided to haul it to the seashore to be burned. The epidemic is now rapidly subsiding.

Health Benefit Societies

In April 1922, when severe business depression resulted from the great war, a consumers' association in a highland district established for the first time a medical department as a means of relieving the union of the heavy burden of medical treatment of its farmer members. The following month another union was founded. These are said to have been the first health benefit groups in this country. At that time hardly any attention was given to it, but it has become a menace to all medical men today. Now the Department of Agriculture and Forestry has put its hand to the establishment of "health benefits," with the powerful aid of the Central Association of the Japan Industrial Guild. Notwithstanding the strong opposition by the medical associations central and local, it has grown rapidly. There were in 1932 only twenty-six health benefit societies, in 1935 there were ninety-one. At the end of November 1936 the number amounted to 805. The unions are found in eighteen cities, 356 towns, 1,548 villages, and forty hamlets, and the number of members exceeds 500,000. At the same time public institutions, great industries, mines and large manufacturers show a tendency to establish a medical office of their own for their workers. The practitioners here are also going to be excluded. The graduates of medical colleges, of

late, seem to prefer to be panel doctors, perhaps thinking it a safe way to make a living. The college authorities are eager to send their graduates to new districts as panel doctors. They encourage the town authorities to form a new union, thus helping to increase the health benefit unions. The Japan Industrial Guild, the most powerful association of this kind, has much capital and influence over all the farm villages. It has recently made public a three year plan of expansion of the health benefit societies all over the country. The guild is said to oppose the plan of the government in dealing with medical matters.

Movement to Encourage Use of Domestic Medical Supplies

The Home Office, soon after the outbreak of the Sino-Japanese conflict, held a meeting to encourage the use of home-made medical articles, summoning all the chief manufacturers of medicine or "patent" medicine. One of the chief aims was to have a continuous supply of all kinds of medicine and to prevent a sudden rise in price, even if the foreign supply might have to be stopped. There was to be made a list of all available medicine, distributed far and wide among the practitioners. The list also shows the comparative effect of home-made medicines and the foreign products. In 1935 the home-made medicines and articles amounted to the sum of 140,000,000 yen, which showed rapid progress in this industry. On the other hand, the imported medicines and articles in that year amounted to 20,000,000 yen. It has almost been settled how to substitute home-made articles for foreign ones. This movement is to include dental medicines and articles. The dental association of Japan has long been engaged, under the guidance of the Home Office, in the supply of genuine home-made articles. With two or three exceptions, almost all the articles now in use by the dentists here are home-made ones.

Number of Dentists and Pharmacists

According to an investigation made in December 1935 the number of dentists was 21,067, while in the previous year there were 20,080. There were 274 dentists to 10,000 of the population. The pharmacists amounted to 26,732, and this is an increase of 1,775 when compared with the previous year. Each 10,000 of the population has 380 pharmacists, of whom 3,009 are working in the hospitals or clinics, while 1,683 are engaged in selling medicine.

Death of Dr Ikeda

Dr Yoichi Ikeda, one of the most prominent gynecologists, died at the age of 80, September 8, at Fukuoka in the house of his eldest son, Dr Kazuo Ikeda, who is a surgeon. He was born in Saga in 1859 and graduated from the Tokyo Imperial University in 1883. He was well versed in German. The Japan Gynecologic Society owes its foundation in 1902 to him.

Marriages

- EUGENE FLYNN, Corpus Christi, Texas to Miss Birdie Kenny of Galway, Ireland, in Dublin, Ireland, July 3.
FRANK ELMORE WILSON, Mooresville, N. C., to Miss Esthier Coleman Hambley, at Salisbury, in November.
RALPH M. LAUGHLIN, Tipton, Iowa, to Miss Geraldine O'Neil of Milwaukee, in Clinton, Iowa November 8.
JAMES E. WHITMIRE, Sumner, Iowa, to Mrs. Virginia Amsden Goen of Manchester, November 13.
CLAYTON L. INGWELL, Deerfield Wis., to Miss Fern Frances Nieland of Madison, November 11.
ALVIN O. HENDRICKSON, Fairchild, Wis., to Miss Maxine Hartwig of Madison, October 30.
LEWIS GRANT JACOBS to Miss Catherine Feeney, both of Madison, Wis., October 30.
ALDEN F. RISSER, Stewartville, Minn., to Miss Marion Fran of Minneapolis, October 9.

Deaths

Arthur Davenport Black * Chicago, Northwestern University Dental School, Chicago, 1900, Northwestern University Medical School, Chicago, 1901, for twenty years dean of the Northwestern Dental School, and a member of the faculty since 1900, as professor of oral surgery, operative dentistry and oral pathology, a director of the Chicago Tuberculosis Institute, fellow of the American College of Surgeons, was an honorary member of scientific societies in America and abroad, including the Royal Society of Medicine of England, the German Academy of Natural Sciences and the Swedish Dental Society, past president of the Illinois State Dental Society, the American Institute of Dental Teachers and the International Association for Dental Research and served for several years on the National Research Council, in 1933 president of the Chicago Centennial Dental Congress, during the World War was advisor to the Surgeon General of the Army, in Washington, for twelve years served on the staff of St. Luke's Hospital, was the author of the "Index of Periodical Dental Literature," consisting of thirteen volumes, author and editor of four volumes of G. V. Black's work on "Operative Dentistry", aged 67, died, December 7, in the Swedish Covenant Hospital, of myelogenous leukemia

Francis A. Long * Madison, Neb., State University of Iowa College of Medicine, Iowa City, 1882, member of the House of Delegates of the American Medical Association, 1907, 1908 and 1911, president of the Nebraska State Medical Association, 1906-1907, one of the founders, past president and secretary of the Elkhorn Valley Medical Society, fellow of the American College of Surgeons, surgeon to the Union Pacific Railroad, served continuously since 1916 as chairman of the publication board and since 1920 editor of the *Nebraska State Medical Journal*, aged 78, died, November 24, of coronary thrombosis, chronic myocarditis and nephritis

John Woodford Farlow * Boston, Harvard University Medical School, Boston, 1877, for many years instructor in laryngology at his alma mater, past president of the American Laryngological Association, and the Medical Library Association, at various times associated with the Carney Hospital, Boston City Hospital, Free Hospital for Consumptives and the Boston Dispensary, formerly librarian of the Boston Medical Library, aged 84, died, September 24, at his summer home in Manchester

William Warren Hildreth, New York, Columbia University College of Physicians and Surgeons, New York, 1910, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, associate clinical professor of obstetrics at his alma mater, on the staffs of the Sloane Hospital for Women, New York, Nassau Hospital, Mineola, and the Tarrytown (N. Y.) Hospital, aged 53, died, October 18, of cerebral hemorrhage

Edgar Raymond Hiatt * Troy, Ohio, Indiana University School of Medicine, Indianapolis, 1916, past president of the Ohio Public Health Association, city and county health officer, and formerly health officer of the City of Logan and of Hocking County served during the World War, aged 49, died, October 12, in the Stouder Memorial Hospital, of pernicious anemia and disease of the gallbladder

John Ernest Greiwe * Cincinnati, Medical College of Ohio, Cincinnati, 1889, formerly adjunct professor of medicine and lecturer on physical diagnosis at his alma mater, past president of the Cincinnati Academy of Medicine, fellow of the American College of Physicians, aged 72, died, October 28, in the Good Samaritan Hospital, of cerebral thrombosis

Frank John Colgan, Rochester, N. Y., University of Michigan Homeopathic Medical School, Ann Arbor, 1910, member of the Medical Society of the State of New York, served during the World War, member of the city health department, on the staffs of the Highland and Genesee hospitals, aged 49, died, October 12, of coronary thrombosis

Harry Adler * Baltimore, University of Maryland School of Medicine, Baltimore, 1895, formerly director of the clinical laboratory, associate professor of gastroenterology, professor of therapeutics and professor of clinical medicine at his alma mater, on the staff of the Sinai Hospital, aged 65, died, November 1, of heart disease

Ludwig Frederick Hooge * Chicago, Chicago Homeopathic Medical College, 1889, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 73, on the staff of the South Shore Hospital, where he died, October 7, of coronary thrombosis

Charles Frederick Friend, Chicago, Hering Medical College, Chicago, 1895, member of the Illinois State Medical Society, formerly a medical missionary in Africa, on the staff of the Evangelical Hospital, aged 72, died, October 2, of carcinoma of the gallbladder and acute pancreatitis

Yepros Martin Doodokyan, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, member of the Illinois State Medical Society, aged 62, died, October 16, of mitral insufficiency, chronic nephritis and arteriosclerosis

Jack Martin Estes, Abilene, Texas, University of Texas School of Medicine, Galveston, 1899, member of the State Medical Association of Texas, aged 63, was killed, October 10, near San Fernando, Calif., when struck by an automobile

John H. Drach, Cockeysville, Md., University of Maryland School of Medicine, 1880, member of the Medical and Chirurgical Faculty of Maryland, aged 77, died, September 11, in the Maryland General Hospital, Baltimore

Thomas H. McCann, Portsmouth, Ohio, Kentucky School of Medicine, Louisville, 1894, member of the Ohio State Medical Association, formerly member of the city council, aged 73, died, September 3, at Minford

John Thomas Peery, Corcoran, Calif., University of Southern California College of Medicine, Los Angeles, 1906, member of the California Medical Association, aged 61, died in September

James Manuel Johnson * McLeansboro, Ill., University of Illinois College of Medicine, Chicago, 1930, aged 35, died, September 24, in the Barnes Hospital, St. Louis, of infantile paralysis

George Joseph Moser, New York, University of the City of New York Medical Department, 1878, member of the Medical Society of the State of New York, died, September 26

Alfred Abraham Citrynell, Governors Island, N. Y., Emory University School of Medicine, Atlanta, 1933, on the staff of the Station Hospital, aged 37, died, September 14

John William Berryman, Scottville, Ill., Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1902, aged 77, died, October 17, of carcinoma of the stomach

James Enoch Vogan, Youngstown, Ohio, Western Pennsylvania Medical College, Pittsburgh, 1891, aged 76, died, September 24, of pneumonia, following an operation

Samuel Wilson, Yatesville, Ga., University of Georgia Medical Department, Augusta, 1891, member of the Medical Association of Georgia, aged 71, died, September 28

John Henry Brett * Cleveland, Western Reserve University Medical Department, Cleveland, 1904, chief surgeon at the Woman's Hospital, aged 54, died, September 2

Cullen O. Thomas, Worthington, Mo., Central Medical College of St. Joseph, Mo., 1903, member of the Missouri State Medical Association, aged 60, died, September 9

Jacob Haas, New York, Eclectic Medical College of the City of New York, 1903, member of the Medical Society of the State of New York, died, September 23

Gustave E. F. Anderson, Los Angeles, Rush Medical College, Chicago, 1893, formerly member of the city board of education, aged 74, died, September 17

John Shepherd Eastland, Judsonia, Ark., Philadelphia University of Medicine and Surgery, 1870, Civil War veteran, aged 92, died, October 8, of senility

George Albert McDonald, Fairfield, Ill., Hahnemann Medical College and Hospital, Chicago, 1895, aged 72, died, September 28, of acute endocarditis

Dennis L. Hill * Wickham, W. Va., Chicago Medical School, 1920, mayor of Mabscott, aged 47, died, September 19, in a hospital at Beckley

Peter H. Fitzgerald, Woodburn, Ore., Willamette University Medical Department, Salem, 1886, aged 79, died, September 14

Samuel Milton Humphreys, Columbus, Ohio, Ohio Medical University, Columbus, 1900, aged 62, died, October 29

Claes William Johnson, Claremont, Calif., Rush Medical College, Chicago, 1880, aged 81, died suddenly, October 9

James Henry Turner, Brooklyn, College of Physicians and Surgeons of Chicago, 1891, aged 79, died, September 24

J. W. Wisely, Kalamazoo, Mich., Chicago Homeopathic Medical College, 1887, aged 80, died, September 19

Henry Fidler * New York, Long Island College Hospital, Brooklyn, 1907, aged 61, died, October 1

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Table Gee Valuable Elements of Milk—Table Food Concentrates Inc. Chicago Composition not given. Fraudulently represented as a palatable food containing extra milk units for growth in the young and for tissue repair in both young and old aiding digestion and elimination.—[N J 26487 May 1937]

Epsolin—Union Products Co. New York. Falsely represented as producing certain physiological effects through the action of epsom salt whereas these were due to the phenolphthalein and aloin present.—[N J 26488 May 1937]

Four Leaf Clovers—Pilgrim Co. Chicago Composition Essentially boric acid borax starch and a pink coloring matter. Fraudulently represented as a remedy for female disorders including leukorrhea and as an antiseptic.—[N J 26499 May 1937]

Mentos—Mentos Products Inc. Philadelphia Composition Essentially sulfur borax ammonia and water with small amounts of perfume. Fraudulently represented to grow hair stop dandruff and scalp disorders eczema sores etc.—[N J 26500 May 1937]

Italina Effervescent Salts—F. Bonomo & Co. Trieste Importing Co., and Louis Lapone New York Composition Essentially phenolphthalein baking soda tartaric acid citric acid and sugar flavored with lemon oil. Misbranded in being falsely represented as consisting wholly of effervescent salts and a lemon product and fraudulently represented as a remedy for stomach troubles excesses in eating and drinking etc.—[N J 26505 May 1937]

Owl Elixir Iron Quinine and Strychnine—United Drug Co. and Owl Drug Co. San Francisco Composition A liquid containing quinine sulfate flavored with orange. Fraudulently represented as an effective treatment for wasting diseases malaria, etc.—[N J 26504 May 1937]

Mineral Life—Mineral Life Laboratories Inc. Des Moines Composition Essentially sulfur dioxide (0.1 per cent) sulfuric acid (0.04 per cent) salts of sodium potassium calcium magnesium manganese iron copper (0.1 per cent) and water (approximately 99.75 per cent). For inflammation ulcerations catarrh sinus trouble etc. Fraudulent therapeutic claims.—[N J 26508 May 1937]

Universal Tonic Ginseng—J. I. Van Cleave trading as Universal Medicine Co. Portland Ore. Composition Essentially extracts of plant drugs alcohol (27 per cent by volume) glycerin and water. Fraudulently represented as a remedy for stomach liver kidney and nervous disorders.—[N J 26510 May 1937]

Syl Way—Health Foundation of California Los Angeles Composition Essentially dried yeast dried milk cane sugar corn starch cereal germ and ground seeds resembling psyllium. For colitis malnutrition etc. Fraudulent therapeutic claims.—[N J 26515 May 1937]

Vegetate Formula BF 1 (Tablets)—Health Foundation of California Los Angeles Composition Essentially rice bran dried okra seaweed cinnamon cranberry and leaf tissue including a small amount of alfalfa leaf. Fraudulently represented as a remedy for hyperacidity bloating etc.—[N J 26513 May 1937]

Vegetate broth—Health Foundation of California Los Angeles Composition Essentially dried yeast dried alfalfa onion tomato cereal flour red pepper celery seed okra and common salt. Fraudulently represented as a mineral broth scientifically compounded to retain valuable minerals which 'Brings you life anew'.—[N J 26515 May 1937]

Milam Herb Compound—Milam Inc. Charlotte N. C. Composition Essentially extracts of plant drugs including a laxative and small proportions of nitric and salicylic acids. For impure impoverished or acid blood all run down and depleted conditions. Fraudulent therapeutic claims.—[N J 26516 May 1937]

Tricasco—Tricasco Laboratories Chicago Composition Essentially water sugar and extracts of plant drugs including licorice. Fraudulently represented as a remedy for gallstone weak eyes gravel tuberculosis pneumonia arthritis and many other disorders.—[N J 26521 May 1937]

Lees (L. G. C.) Herbal Compound—Eric Laboratories Cleveland Adulterated in falling below the professed standard or quality represented as it contained no potassium iodide iron iodide or significant amounts of iron peptonate or sodium salicylate. Misbranded because alcohol content was not declared on the label fraudulently represented as a remedy for skin liver and blood disorders arthritis fevers etc.—[N J 2652 May 1937]

Ward's Vitamized Tonic Tablets—Savoy Drug & Chemical Co. Chicago Adulterated in that the strength and purity fell below the standard of vitamin units declared misbranded because of false and misleading claims.—[N J 26524 May 1937]

Bromo Foam—Chancey A. Jones trading as the Bromo-Foam Co., Tiffin Ohio Composition Essentially baking soda (65 per cent), common salt (3.87 per cent) sodium salicylate (3.44 per cent), sodium bromide (2.90 per cent) caffeine (0.51 per cent) and citric acid flavored with peppermint oil. Fraudulently represented as a cure for indigestion headache stomach disorders etc.—[N J 26951 July 1937]

Eczematone—Barlow Chemical Association Oklahoma City Composition Essentially corrosive sublimate a trace of boric acid alcohol (84 per cent by volume) and water. For scalp disease eczema acne dandruff falling hair etc. Fraudulent therapeutic claims.—[N J 26952 July 1937]

Eczematone Ointment—Barlow Chemical Association Oklahoma City Composition Essentially mercury and a mercury compound in an ointment base. Fraudulently represented as a remedy for eczema scrofula, and all other skin disorders.—[N J 26957 July 1937]

Curarina De Juan Salas Nieto—Richard Diener trading as Curarina Agency Oxnard Calif. Composition Essentially a water alcohol solution of drug extractives containing about 34 per cent of alcohol by volume with traces of resin saponin like glucosides and alkaloids. Fraudulently represented as a cure for disorders of the blood and heart, scatica, rheumatism malaria diabetes, typhoid fever smallpox etc.—[N J 26959 July 1937]

Dexene—Sanosapor Laboratories Huntington W. Va. Composition Essentially water (99.34 per cent) and sulfur dioxide (1/4 of 1 per cent). Fraudulently represented as an effective treatment for diabetes in conjunction with a recommended diet.—[N J 26960 July 1937]

N. A. No. 7—N. A. Co. Laurel Miss Composition Essentially a solution of epsom salt iron sulfate water and small amounts of calcium manganese aluminum and phosphate. For indigestion rheumatism kidney disorders etc. Not a germicide as represented. Fraudulent therapeutic claims.—[N J 26976 July 1937]

N. A. No. 7 1/2—N. A. Co. Laurel Miss Composition Essentially epsom salt iron sulfate water and small amounts of quinine aluminum phosphate and chloride. Fraudulently represented as a remedy for stomach, liver and kidney disorders malaria etc.—[N J 26976 July 1937]

Runners Combined Eczema Lotion—Earle Chemical Co. Wheeling W. Va. Composition Essentially water alcohol glycerin and boric acid with small amounts of carbolic and salicylic acids and wintergreen. Fraudulently represented as a remedy for eczema scalp disorders itchy and oak poisoning etc.—[N J 26977 July 1937]

Beck's Little Wonder Headache Powders—A. L. Beck Sharon Pa. Composition Essentially acetaminol (4 1/2 grains per powder) caffeine and potassium citrate. Fraudulent representations.—[N J 26979 July 1937]

Ruherb—Keystone Laboratories Inc. Memphis Tenn. Composition Chiefly water sugar epsom salt alcohol small amounts of salicylic acid and plant extractives including emodin arbutin and a trace of alkaloids. Fraudulently represented as a health, blood and nerve tonic, and a cure for indigestion kidney and liver disorders etc.—[N J 26982 July 1937]

Keystone Kidney Bladder Rheumatism Liver and Backache Remedy—Keystone Laboratories Inc. Memphis Tenn. Composition Chiefly water sugar alcohol small amounts of potassium acetate methenamine juniper oil benzoic acid and plant extractives. Fraudulent therapeutic claims.—[N J 26982 July 1937]

Keystone White Pine Compound Expectorant—Keystone Laboratories Inc. Memphis Tenn. Composition Chiefly sugar water, alcohol plant extractives and chloroform. Fraudulently represented as a cure for coughs and bronchial affections.—[N J 26982 July 1937]

Keystone Antiseptic Healing Oil Liniment—Keystone Laboratories Inc. Memphis Tenn. Composition Essentially small amounts of ammonia water turpentine oil and camphoraceous material a fixed oil and water. Fraudulent therapeutic claims.—[N J 26982 July 1937]

Sphinx Herb Tea (Formerly Munk's System Purifier)—Argyle Laboratories New York Composition Essentially senna leaves and pods with small amounts of fennel and anise seeds elder flowers buckthorn bark dog grass orange peel ginger root and safflowers. Fraudulently represented as a remedy for blood poisoning colitis dizziness etc.—[N J 26990 July 1937]

Vagil Anti Septikones—Eric Laboratories and Mrs. Bee's Health Laboratories Cleveland Composition Suppositories containing hydroxyquinoline in cocoa butter. Fraudulently represented as a remedy for leukorrhea.—[N J 26984 July 1937]

Henry's Deep Rock Oil—Henry Evans Washington D. C. Composition Essentially a petroleum oil a tar oil such as cade, with wintergreen turpentine and oil of cadeput. For pain kidney and bladder disorders asthma rheumatism weak lungs etc. Fraudulent therapeutic claims.—[N J 26985 July 1937]

Gay—Strong Cobb & Co. Inc. Cleveland Composition In each tablet 21 grains of acetylsalicylic acid 17 grains of phenacetin 0.25 grain of caffeine and plant material including viburnum. Fraudulently represented as a prompt relief for menstrual pain and as containing no harmful drugs.—[N J 26987 July 1937]

Rawleigh's Nasal Relief—W T Rawleigh Co, Freeport Ill Composition Essentially menthol camphor and chlorbutanol Fraudulently represented as a remedy for nasal catarrh, hay fever, etc—[N J 26991 July 1937]

Mido—General Drug Co New York Composition In each tablet essentially 49 grains of aminopyrine and 0.4 grain of caffeine Fraudulently represented as a harmless remedy for menstrual pain headache and neuralgia—[N J 26992 July 1937]

Astypodyne Ointment—Astypodyne Chemical Co, Wilmington N C Composition Pine oil (12 per cent) in petrolatum Fraudulently represented as a remedy for hemorrhoids—[N J 26993 July 1937]

Stoco for Colds—Stowe Co Charlotte N C Composition Essentially acetanilid (5 grains per fluid ounce) alcohol caffeine, phenol phthalein salicylates ammonium chloride menthol sugar water flavoring oils emodin bearing drugs and plant extractives including licorice Fraudulent therapeutic claims—[N J 26994 July 1937]

Grams (Dr) Grandmother Medicine—Grams Medicine Co Cuyahoga Falls Ohio Composition Essentially powdered plant material containing aloë an emodin bearing drug and ginger For all blood liver kidney and stomach diseases, diabetes, cancer, etc Fraudulent therapeutic claims—[N J 26999 July 1937]

Correspondence

THE SEASONAL INCIDENCE OF ACUTE CORONARY OCCLUSION

To the Editor—A communication from Dr Paul D Rosahn (THE JOURNAL, October 16, p 1294) analyzed statistically the data on the seasonal incidence of acute coronary artery occlusion presented by Drs Dack, Jaffe and myself in an article entitled "Factors and Events Associated with the Onset of Coronary Artery Thrombosis" in THE JOURNAL, August 21. We divided the seasons into autumn-winter (October to March inclusive) and spring-summer (April to September inclusive). The difference in the incidence of coronary artery occlusion in these two groups was only 2.6 per cent. Dr Rosahn states that "when, however, a slightly different division of the published data is made, a wholly different conclusion results"

Monthly Mean Temperature, New York City

	1930	1931	1932	1933	1934	1935	Average
January	33.5	33	43	40	34.5	29	35.0
February	37	34	36	34	20	31.5	32
March	40	40.5	37	35	37	43	39
April	47.5	40.5	48.5	50	49.5	49.5	49
May	62.5	60.5	61	63	62.5	59	61.5
June	72	69.5	60	71	72.5	68.5	70.5
July	70	76.5	74	73.5	76	76	75
August	73	74.5	75	74	70.5	73.5	73.5
September	71	71	67.5	69	65	64	68.5
October	60	60.5	57.5	56	54	57	56.5
November	46	51.5	43.5	42	45	48.5	46.5
December	35	40.5	50	33	33.5	30.5	35

This slightly different division" consists of winter-spring (December to May inclusive) and summer-autumn (June to November inclusive). Dr Rosahn pointed out that when this is done the difference in incidence becomes 8.8 per cent which may be significant from a statistical standpoint. However, this grouping is not, in our opinion, quite relevant to the problem of the influence of cold weather in New York City. We could not present, within the space limits of our original communication, data on the monthly mean temperature for New York for the years 1930-1935, published by the U S Department of Agriculture, Weather Bureau, Publication 1030, reproduced herewith. On the basis of these data, our grouping includes the five coldest months of the year. Dr Rosahn's arrangement, on the other hand, combines only four of the coldest months. Furthermore, it includes May and omits November in the "cold" season group, although the mean temperature of May was 61.5 F, while that of November was 46.5 F. It is thus

apparent that, with regard to cold, our grouping is the logical one. Dr Rosahn was not aware, of course, of the temperature data.

Dr Rosahn considers statistically significant the high incidence of attacks in January. We have had the invaluable assistance of Alfred J Lotka, the assistant statistician of the Metropolitan Life Insurance Company, who believes that there is some justification in Dr Rosahn's conclusion. However, several facts point to the correctness of our previous conclusion that coronary artery occlusion occurs irrespective of season or temperature. Thus it will be noted that the coldest month of the year, February, had next to the lowest incidence of attacks. Furthermore, in 237 additional cases observed since the original data presented were collected the highest incidence was in March, the third coldest month of the year. On the other hand, February, the coldest month, had an incidence only slightly more than half that of March.

It is obvious that a much larger series of cases will have to be studied to determine conclusively the influence of temperature on coronary occlusion and the significance of the increased incidence in January obtained in our original series. The relation of cold to angina pectoris has been erroneously applied, we believe, to coronary artery occlusion. In any case it is probable that the conclusions of previous writers, such as Wood and Hadley, who found that 87 per cent of attacks occurred in winter and only 13 per cent in summer, are unjustified.

We hope in the future to present the problem of the influence of weather and temperature on coronary artery occlusion in greater detail.

ARTHUR M MASTER, M D, New York

RESUSCITATION

To the Editor—In THE JOURNAL, November 6, Prof Yandell Henderson discusses resuscitation of the new-born, particularly as it applies to the E & J resuscitator. With no attempt to question in any way the background of facts on which Professor Henderson draws his conclusions, it seems fair to point out that much of the argument used by him to sustain his thesis is hardly germane to the conclusions he draws.

At least one source of conflict rests on an improper use of terms. To speak of resuscitation in the new-born is a misnomer, when one is considering the initiation of respiration in an organism that has never breathed. Asphyxia neonatorum and asphyxia due to carbon monoxide gas are two different conditions, and the approach to the treatment of one may not be the approach to the treatment of the other. The attempt to apply to the problems inherent in the former the therapeutic principles applicable to the latter in appraising any type of resuscitator, is misleading and incorrect.

The reports of the commissions which Professor Henderson mentioned were concerned with shock and asphyxia due to gases. It is hardly to be supposed that the valuable observations of these commissions could be logically carried to the point of applying to an instrument designed to initiate respiration in an infant that had never breathed. Few who have interested themselves in the problem will disagree with Professor Henderson's conclusions that an instrument of this kind is irrational in asphyxia neonatorum, but there are many who with justification will disagree that the answer has been found in the Meltzer-Flagg technic. To many the procedure of inflating the infant lung as one would a balloon is abhorrent on both anatomic and physiologic bases. It is to be suspected that this first effort which opens the door to extra uterine life has implications more subtle than a bicycle tire. In the present state of disagreement it would seem premature to put the final stamp of approval on one method or another. If we are to believe the excellent studies reported in the November issue of *Surgery, Gynecology and Obstetrics* by Wilson, Torrey and Johnson

there is compelling experimental evidence that forceful inflation of the infant lung even when done under extreme control is not only useless but as unsound physiologically and harmful anatomically as any respirator or pulmotor. It would be interesting and instructive to see more work done on this subject and meanwhile adhere to conservative measures that are known to be free from danger.

J LYMAN HURLBUT, M.D., Mount Kisco, N. Y.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DIAGNOSIS OF FEVER AND ABDOMINAL PAIN IN BOY

To the Editor—A boy aged 10 years had some indigestion for four or five months that did not respond well to the usual alkaline treatment. Pain was made worse by taking of rich sauces, pickles and potatoes or preserved fruit in large quantities. Four weeks ago pain developed over most of the abdomen but especially the upper part. He complained of pain also in the lower part of the chest anteriorly and posteriorly, more frequently on the right side. The blood count revealed 3,900,000 red cells and 12,000 white cells with 75 per cent polymorphonuclears. Hemoglobin was 75 per cent. The Mantoux test was strongly positive but tests for typhoid undulant fever and paratyphoid fever were all negative. X-ray examination of the chest and gastrointestinal tract gave negative results. The temperature went as high as 103.8 F and the pulse to 90. In one week the temperature came down to 99.4 but went up again to 101 and stayed high for a few days gradually diminishing to 99 again with the pulse 80. Nearly all pain and tenderness have cleared up but with sudden elevation of temperature the epigastric distress returns with attendant loss of appetite. Urinalysis and X-ray examination of the gallbladder region are reported negative. Repeated blood counts have been as before while the temperature still was high. Now at the end of the fourth week the temperature still goes to 99 and 99.4. The boy has not shown any signs of cough or any other respiratory involvement. Will you kindly suggest what might be done further toward arriving at the etiology and treatment in this case?

M.D. Washington

ANSWER—The strongly positive Mantoux test indicates that the child is allergic to tuberculo-protein, which means that a primary tuberculosis complex is still active somewhere in the body, the most common location being in the lungs and adjacent glands. Only 25 per cent of these lesions are demonstrable roentgenologically. It is not uncommon for the tuberculous infection to spread from the tracheobronchial glands downward in the lymphatics to the mesenteric glands. Vague abdominal pain and fever might be caused by exacerbations in these glands. Unless a flat plate of the abdomen revealed calcification in these glands, clinical diagnosis could only be surmised. A normal sedimentation time of the red cells would practically rule out progressive tuberculous infection. Early Pott's disease of the lower thoracic or upper lumbar vertebrae should be excluded by X-ray examination, as referred pain from this source could cause fever and pain. Diaphragmatic pleuritis on a tuberculous basis could also cause the pain.

Early active rheumatic fever or rheumatic heart disease frequently produces upper abdominal pain. A normal sedimentation time would speak against this as would a normal electrocardiogram. Ready response of the pain and fever to salicylates would cause suspicion of rheumatic infection.

Peptic ulcers in children do occur and are often missed unless there is skilled X-ray interpretation, as they produce vague epigastric distress.

A Meckel's diverticulum can become ulcerated and inflamed, causing occasional fever and upper abdominal pain. Blood in the stool on a meat free diet is suggestive in this condition.

Small epigastric hernias, while not accounting for the fever, could cause vague epigastric distress and pain.

Study of the stool for parasites and ova might help in the diagnosis. A differential blood count often shows eosinophilia in these conditions.

Repeated urinalysis should be done, as occasionally pyuria will not be obvious in every specimen.

Colitis of various types must be considered but repeated stool examinations for blood, mucus and pus would aid in this diagnosis.

Vague rarer diseases that cause recurrent fever with abdominal pain are Hodgkin's disease and similar conditions, which could be diagnosed only by biopsy of an enlarged cervical node, if these nodes are enlarged.

One may be dealing with two distinct conditions: (a) upper abdominal distress or (b) fever from a different cause which accentuates any feeling of distress. The fever might be from recurrent tonsillitis or nasal sinusitis.

If all other tests prove negative but the Mantoux test is positive and there is a rapid sedimentation time of the red cells, one would strongly suspect that tuberculous mesenteric adenitis is the cause of the fever and upper abdominal pain. On the other hand, one must be certain that recurrent upper respiratory infections such as tonsillitis are not the cause of the fever accompanied now by abdominal pain, no matter what the original distress may have been from.

Treatment depends on etiology, but moderate rest, general hygienic treatment, bland diet, sunshine and fresh air would be indicated in any condition.

AMPUTATION STUMP INFECTION WITH BACILLUS PYOCYANEUS

To the Editor—Following a knee amputation for diabetic arterio-sclerotic gangrene of the foot there was an infection of the stump with *Staphylococcus aureus* (hemolytic) and *Bacillus pyocyaneus*. The staphylococcal part of the infection has responded to treatment with staphylococcus toxoid and antitoxin. The pyocyanus infection however has responded only slightly to the usual methods of hot compresses and the usual disinfectants such as merthiolate, aluminum acetate diluted solution of sodium hypochlorite and hexylresorcinol. There is abundant pus with gram negative rods. There is free drainage of every part of the wound. Can you advise me of any known specific for *Bacillus pyocyaneus* infections locally or systemically? If there is no known specific what method of treatment would you suggest for the infection?

M.D. California

ANSWER—As far as is known, there is no specific treatment for *Bacillus pyocyaneus* infection. A good method of treatment is to scrub the wound thoroughly with soap and water, to expose it to the sunshine, if available, for half an hour and, if any pocket of pus has formed in the stump, to drain it. Disinfectants such as mentioned are of no particular help. Soap and water was found most helpful during the war.

POSSIBLE ANILINE POISONING

To the Editor—A white man aged 59 who has worked with aniline dyes for the past thirty-five years has been getting attacks of colicky pain in the upper part of the abdomen about once a week for the past year. The pains are severe enough to produce shock and require morphine. He has had a chronic cough for the past five years and marked constipation with occasional diarrhea for three years. There is no history of syphilis or lead poisoning. The hemoglobin is 60 per cent (Taillqvist). The urine is dark brown and is negative for blood. No laboratory work has been done. Are these symptoms consistent with a diagnosis of chronic anilism? Please outline method of procedure and bibliography of clinical articles. The dyes concerned are chrysoidine, methylene blue, metanil yellow, stilbene yellow, nigrosine, basic brown, bismarck brown and auramine.

M.D. New York

ANSWER—This query furnishes no information whether the worker concerned was engaged in the manufacture of these dyes or only in their application, such as in a dye house. In either case it is probable that the worker was exposed to large numbers of other chemicals, such as varied intermediates in dye manufacture or various mordants, bleaches and fixing agents such as are used in connection with dyes. On the assumption that the condition has been acquired at work, it is highly probable that no single agent, such as aniline, or any one dye is to be regarded as responsible. Instead, such conditions ordinarily must be attributed to "mixed" intoxication, in which large numbers of substances to which exposures may have been provided during the thirty-five years of employment have contributed some part. While the manifestations mentioned are not inconsistent with the diagnosis of an occupational disease when properly supported by additional laboratory work, it must be recognized that the same type of manifestations in a person aged 59 frequently arise in the entire absence of exposures to chemicals in the course of employment. Before diagnosis of an occupational disease is made, more extensive laboratory work should be carried out including appropriate gallbladder and gastrointestinal X-ray examinations and complete blood examination including tests for methemoglobin. If benzene is employed in the manufacture of dyes, and if the worker is still exposed, urine sulfate tests should be carried out. This test is described in the *Journal of Industrial Hygiene* 18:349 (June) 1936. Chronic aniline poisoning is quite rare. The following are widely regarded as typical manifestations of

chronic aniline poisoning anemia, slowing of the pulse, disorders of digestion, such as eructations, loathing of food, vomiting, diarrhea, and eczematous and pustular eruptions on various parts of the body, especially on the scrotum, nervous symptoms, general debility, headache, ringing of the ears, vertigo, unrestful sleep, disturbances of sensibility, often also of motility and spasmodic muscular pain. Anemia and retarded pulse are early symptoms. The blood is of a brownish hue but microscopically unchanged, occasionally the urine contains blood (Kober and Hayhurst). CALCAREOUS DEGENERATION OF ARTERIES

To the Editor—What is the best treatment for senile calcareous degeneration of the external iliac and femoral arteries? I am interested in the graphic method.

C M DESVERAINE MD Havana Cuba

ANSWER—There is no specific treatment for calcareous degeneration of the arteries. The treatment of this condition is the same as the treatment of generalized arteriosclerosis, which, as is well known, is unsatisfactory. Roentgenologic evidence of arteriosclerosis of the peripheral arteries is commonly found in instances in which evidence of impairment of the arterial circulation is absent. It is not until thrombosis occurs that the blood transporting function of the arteries is reduced. When there is diminution of circulation to the extremities, treatment becomes complex and can be presented only briefly here.

The chief aim of treatment is the prevention of gangrene, the program for which is the same as has been so well publicized for the prophylactic care of the feet in diabetes. Trauma should be avoided, new shoes should be worn for only short periods until thoroughly broken in, protection from cold is essential, and application of strong solutions containing iodine and phenol and other irritating substances is sharply interdicted. Such preparations although well tolerated by patients with normal circulation may lead to ulcers or gangrene in patients with impaired circulation. Trichophyte infections should be treated by the immersion of the feet in solutions of potassium permanganate rather than by application of solutions containing iodine or salicylic acid.

Postural exercises consist of alternate elevation and dependence of the extremities for periods of one minute each for fifteen minutes, two or three times daily. These exercises tend to increase the collateral circulation. Alternate immersion of the extremities in water of approximately 40 and 105 F for periods of one minute each, for thirty minutes three times daily, seems to help. The extremities may be warmed by exposing them to heat from one or two carbon filament bulbs in cabinets such as are commonly used in the treatment of arthritis. The temperature should not exceed 100 F. Theobromine and nicotin may increase the circulation to the extremities.

The artificial induction of fever by the intramuscular injection of sulfur in oil produces a sharp fever and temporarily increased circulation, which in many instances is valuable. Intermittent suction and pressure (passive vascular exercise) should be carried out for periods of not less than two or three hours daily. The application of diathermy to the thighs increases the circulation and may be of some value in treatment. Recently there have been reports of benefit following intermittent venous obstruction by inflating the cuff of a blood pressure apparatus placed about the thigh to the diastolic pressure for two minutes and then deflating it for two minutes over periods of several hours daily. However, this has been of little or no value in the hands of some physicians.

The use of insulin free pancreatic extracts or striated muscle extracts may increase the distance a person can walk before the distress of claudication occurs.

When medical treatment does not control the pain when the patient is at rest, section crushing or injection of the peripheral nerves or intraspinal injection of alcohol may be carried

out in selected cases. When gangrenous ulcers are painful, some relief may follow the application of anesthetic agents.

EFFECTS OF OXYGEN

To the Editor—Are there any deleterious effects in a patient or animal placed daily in an oxygen tent for one or two hours over a long period of time? What will it do to the circulatory system to the nervous system or to the metabolic functions? Please refer me to some literature which may deal in detail with this topic.

M D, Massachusetts

ANSWER—The effect of confinement in an oxygen tent for several hours daily will depend on the concentrations of oxygen and carbon dioxide and on the atmospheric conditions maintained.

In an oxygen tent the oxygen concentration is usually approximately 50 per cent, the carbon dioxide rarely exceeds 1 per cent in the first two hours, provided the tent is well designed and there is normal metabolism and the usual leakage. These concentrations are well within the margins of safety and have no effect on normal people. Fully saturated hemoglobin cannot accept additional oxygen. The carbon dioxide loss will continue to occur at the normal rate across the interface pulmonary blood alveolar air. Nurses have remained on duty for periods of from three to four hours at a stretch daily in oxygen chambers without detectable change in their condition. Patients who have diminished pulmonary circulation either by reason of cardiac weakness, emphysema or bronchitis may be benefited by a sojourn of several hours a day in tents or chambers. This benefit may be the result of temporary increase in oxygenation of the blood and consequent improvement in circulation. Patients with severe pulmonary disease and oxygen want must be provided with oxygen at an increased partial pressure continuously. Oxygen tents are usually maintained at lower temperature and humidity and with a greater rapidity of air movement across the face than is present outside. This may induce stimulation of the circulation, reduce metabolism and have a soothing effect on the nervous system.

An excellent bibliography on the physiology and therapeutics of oxygen may be obtained from Linde Air Products Company.

BANANA OIL OR AMYL ACETATE

To the Editor—From an industrial standpoint what are the hazards in the use of so called banana oil? It is used as a solvent in lacquers and often in spray gun work in coating furniture. Just what is banana oil? Can it produce narcosis when carelessly handled or accidentally spilled in a closed room? What other effects can it have when inhaled? Is banana oil sometimes a mixture with benzene and acetone when used as a solvent in lacquer work?

M D Ohio

ANSWER—Banana oil is iso amyl acetate, having the formula $\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$. However, in some industries, common practice attaches the name of banana oil to almost any solvent substance possessing the fruity odor of pears or bananas associated with this substance. It is possible that banana oil, or iso amyl acetate, may be mixed with benzene or acetone for use in spray coating but if so the mixture is not properly termed banana oil. In addition to iso amyl acetate, there are at least two other varieties, namely, normal amyl acetate and secondary amyl acetate. The latter has been investigated by the United States Public Health Service (Patty, I A, Yant, W P and Schrenk H H. Acute Response of Guinea Pigs to Vapors of Some New Commercial Organic Compounds. XI Secondary Amyl Acetate. *Pub Health Rep* 51 811 [June 19] 1936). This secondary amyl acetate in high concentrations produces narcosis terminating in death. Apart from narcosis irritation of the eyes and nasal mucous membrane are the chief manifestations. Iso-amyl acetate frequently has been investigated and reported on in the literature. The Smyth in the *Journal of Industrial Hygiene* (10 261 [Oct] 1928) included

this substance in a general study of lacquer solvents. They state that amyl acetate is considered as among the safest of the solvents investigated. The consensus of investigators everywhere is that iso-amyl acetate usually causes, in exposed lacquer workers, no greater degree of harm than is reflected by minor irritation of the eyes, the upper respiratory tract, the bronchi or other exposed tissues.

IMPOTENCE AND AZOOSPERMIA

To the Editor—A single man aged 32 with impotence and azoospermia, was operated on eight years ago for varicocele of the right cord. Following this operation a complete atrophy of the right testis developed and he has been completely impotent. He is otherwise, in good physical health except for mental depression. He states that he has never had venereal infection and that he has never had any swelling of the left epididymus. Examination of the left testis shows no evidence of past or present disease. The prostate showed a 1 plus enlargement with infiltration of the right vesicle but the left vesicle was not palpable. The expressed secretion showed an average of 50 to 60 leukocytes per high power field and a few leucithin bodies with a great amount of mucus but no spermatozoa or red cells. The prostate was somewhat soft in consistency but not tender. The centrifuged urine showed an average of 15 to 20 leukocytes and an occasional clump of pus cells per high power field. The Wassermann reaction has been negative on repeated examinations. The weight has been stationary for the past few years. The heart and lungs are normal. There is no evidence of spinal cord disease. Cystoscopic examination revealed no abnormalities of the bladder or bladder neck. There were a few granulations in the prostatic urethra and the patient had a rather small verumontanum; the orifices of the ejaculatory ducts appeared normal. There was no stricture of the urethra. The patient is a laborer doing outside work. His blood pressure is 135 systolic, 85 diastolic. I have been massaging the prostate and vesicles and using sounds occasionally with deep instillations of either 10 per cent mild protein silver or 0.5 per cent silver nitrate and diathermy to the prostate. I have used the anterior lobe of the pituitary in ascending doses up to 80 grains (5 Gm.) a day, anterior pituitary extract and antuitrin S, and also androstine subcutaneously. The patient showed some improvement under this therapy as manifested by the return of a few living and nonmotile spermatozoa on some occasions in the expressed secretion, also some reduction in the number of pus cells and an occasional partial erection on awakening. The improvement, however, has been only temporary and the patient has become much discouraged. Please offer any further suggestions that may be of benefit in bringing back his ability to obtain erection and to stimulate the return of spermatozoa. Should the condition be considered hopeless?
M. D., Minnesota

ANSWER—The fact that some spermatozoa were found in the expressed fluid indicates that there is no obstruction in any of the genital tubes, in other words, that the azoospermia is testicular in origin. As this patient has but one normal testicle, the treatment must be continued longer than otherwise and the results will be much slower. Tablets of the anterior lobe of the pituitary are generally considered to be devoid of therapeutic effect by mouth. Androstine was reported by the Council on Pharmacy and Chemistry to be practically inactive by biologic test (*THE JOURNAL*, Jan. 20, 1936, p. 2150). Small doses of thyroid (0.01 Gm.) may be of benefit. In addition, for his impotence, he should receive locally the sinusoidal-faradic current of moderate rapidity and as strong as he can bear without any pain. One cable is connected with a rectal electrode and the other with a wet-sponge electrode applied to the perineum and the current is allowed to pass for about ten minutes. Treatment may be given twice a week.

TEST FOR AMYLOIDOSIS

To the Editor—What tests may be used to determine the presence of amyloid disease and what is the efficacy of these tests?

VICTOR S. RANDOLPH, M.D., Phoenix, Ariz.

ANSWER—The only practical clinical test for amyloidosis is the intravenous injection of congo red, first proposed by Bennhold (*Deutsches Arch. f. klin. Med.* 142:32 [March] 1923). This dye had been used previously for the determination of plasma volume (Keith, N. M., Rowntree, L. G., and Geraghty, I. T. A Method for the Determination of Plasma and Blood Volume, *Arch. Int. Med.* 16:547 [Oct.] 1915; Griesbach, *Deutsche med. Wchschr.* 47:1289 [Oct. 27] 1921). Since the original description by Bennhold, the reliability of the test has been confirmed by numerous authors (Bookman and Rosenthal, *Am. J. M. Sc.* 173:396 [March] 1927; Barker, N. W., and Snell, A. M., *J. Lab. & Clin. Med.* 16:262 [Dec.] 1930; Wallace, J. E., *Lancet* 1:391 [Feb. 20] 1932).

The test is performed by the intravenous injection of from 10 to 18 cc. of a 0.75 to 1.5 per cent sterile solution of congo red in distilled water and the withdrawal of blood samples after four minutes and after one hour. Care should be taken to prevent hemolysis. The two serums are compared in the colorimeter with the four minute sample as the standard of 100 per cent. Friedman and Auerbach (*J. Lab. & Clin. Med.* 21:93 [Oct.] 1935) propose that the serums be mixed with 95 per cent alcohol to precipitate any dissolved hemoglobin in the

proportion of 2 cc. of serum to 8 cc. of alcohol. Wallace uses plasma and collects 4.5 cc. of blood in 0.5 cc. of 38 per cent sodium citrate solution. He points out that the plasma volume is never constant and that this method permits that factor to be considered.

If more than 60 per cent of the congo red disappears from the blood in one hour, it may be assumed that the patient has amyloidosis. Loss of from 40 to 60 per cent is of doubtful significance. Normal individuals will show up to 30 per cent and more rarely 40 per cent loss.

Most cases of chronic lipid nephrosis show from 40 to 60 per cent disappearance from the blood, but an examination of the urine will show excretion of the dye in contrast to amyloidosis (Barker and Snell). In diseases of the liver, Bennhold found abnormal retention in the blood but without correlation with the severity of the disease.

The congo red test when properly performed and judiciously evaluated, is of distinct value in the differential diagnosis of amyloidosis.

CORRECTION OF CICATRICAL ECTROPION

To the Editor—Following a fall from a porch a child received an incised wound on her left cheek extending vertically into the left lower eyelid as far as and including the palpebral margin. The wound had open the facial muscles and the orbicularis oculi in the lid. The wound was sutured with interrupted fine silk and healed by primary intention. About four weeks after the injury a cicatricial ectropion was developing as a result of the contraction of the scar. How soon would it be practical to attempt correction of the ectropion and what operative procedures should be followed? The child is able to close the eye, as the orbicularis is normal.

BENJAMIN BRAUDE, M.D., Chicago.

ANSWER—Such a contraction will usually follow a vertical scar which involves both the cheek and the lower lid. It may be corrected by making a transverse incision in the part of the lid that is longest transversely, and throwing into this transverse incision a flap taken from the opposite border of the wound or the incision that results from reopening the cheek scar. With proper undermining this can usually be done. The upper end of the secondary incision that frees this flap should bear such a relationship to the level of the transverse incision that the tissues below this transverse incision will hold up the undermined part of the cheek from which the transverse flap is taken.

Another plan that is occasionally necessary is to relieve the contracture by making a transverse incision through it and spreading the defect until the lid is well up in place, and the resulting defect is then covered with a free skin graft. Such a graft is usually of postauricular skin, since this is thin, takes readily, and matches the skin of the face in color.

The operation should be undertaken any time the eye seems to be suffering from lack of contact of the lid with the globe. Otherwise there is no particular hurry, and often the period of contracture is followed by a period of relaxation as the scar becomes older and softer, thus usually with time the amount of correction necessary is less.

DYSMENORRHEA TREATED BY CAUTERIZATION OF GENITAL SPOTS

To the Editor—A patient, aged 16, has severe attacks of dysmenorrhea. Vomiting occurs during the attack and she is unable to retain any liquids. The only treatment so far has been the administration of capsules each containing aminopyrine 5 grains (0.3 Gm.) extract of hyoscyamus five-sixths grain (0.054 Gm.) and phenobarbital one-half grain (0.03 Gm.) but they fail to prevent the attack. I tried the application of 5 per cent Larocain with only slight improvement in the 'genital spots' which I found to be enlarged and red. I did not have 20 per cent cocaine. I should like to attempt cauterizing these spots but cannot find in my text-book the exact location of the tuberculum septi which with the anterior portion of the inferior turbinates is said to constitute the genital spots. Could you tell me exactly where the tuberculum is? Also how to apply the trichloroacetic acid to the spots.

M. D., New Jersey

ANSWER—The tuberculum septi is a tubercle or prominence on the upper anterior part of the nasal septum. This area and the anterior half of the lower turbinates were called 'genital spots' by Fliess. These areas are invariably swollen more prominent, bleed more readily on slight touch and are exceedingly hyperesthetic preceding and during menstruation (Brettauer, *J. Surg. Gynec. & Obst.* 17:381, 1913). According to Koblanck (*Die Nase als Reflexorgan*, Berlin and Vienna, Urban & Schwarzenberg, 1930) Fliess maintained that the abdominal pain associated with menstruation may be relieved by treating the swellings in the inferior turbinates, and the backaches may be eliminated by reducing the swelling on the septum. The associated gastric symptoms, such as vomiting disappear after applying medication to the left middle turbinate and the headaches vanish after electrolysis of the tubercle on the septum.

The application of trichloroacetic acid is somewhat painful, hence 5 per cent cocaine should be applied to the sensitive spots before cauterizing them with trichloroacetic acid. According to Brettauer it is best to cauterize at intervals of from three to seven days during one intermenstrual period. In some cases this may have to be repeated during one or two successive intermenstrual periods. After each treatment a slough forms. This disappears in about five days, so that about four applications of trichloroacetic acid may be made during one intermenstrual period. The relief in many cases is spectacular. According to Emil Mayer (*THE JOURNAL*, Jan 3, 1914, p 6), permanent relief is obtainable by intranasal treatment in from 50 to 75 per cent of the cases.

BACILLUS PROTEUS INFECTIONS OF URINARY BLADDER

To the Editor—What agents other than *Bacillus acidophilus* will suppress the growth of *Bacillus proteus*? To what extent is the bladder tolerant to local acidifying solutions? What acid solutions would you recommend for irrigating the bladder in order to combat *B. proteus* infection? For a *B. proteus* infection of the urinary tract would you advise a high starch low protein or a ketogenic diet? How efficacious is *B. proteus* vaccine?
M D New York

ANSWER—*Bacillus proteus* can be eliminated from the urine by methods that are more efficient than the injection of *Bacillus acidophilus*. Acidification of the urine by medication will usually cause the urine containing *B. proteus* to be bacteriostatic, provided the pH can be reduced to a sufficiently low level. If the pH of the urine is 7.0 or lower, it will usually not be very difficult to eliminate the organism by this method. However, if the urine is alkaline and the pH is more than 7.5 or 8, it may be extremely difficult to render it acid by any form of medication. It is usually advisable to give either the ketogenic diet or mandelic acid therapy first and give drugs in addition to insure acidification.

Acidification of the urine is best brought about by administration of ammonium chloride or ammonium nitrate. When these are not tolerated, nitric acid or nitrohydrochloric acid may be used, although the latter is not usually as efficacious as the former. In addition to acidification by means of these drugs, chemotherapy or the ketogenic diet should be used.

The ketogenic diet is unquestionably better than a high starch, low protein diet in the elimination of *Bacillus proteus*. A simpler way of obtaining the same result, however, is available in the oral administration of mandelic acid.

Vaccines made from *Bacillus proteus*, either stock or autogenous, have not proved to be of much therapeutic value.

Cystoscopic curettage and topical application of 20 per cent silver nitrate to the areas involved may be employed in cases that are resistant to the remedies suggested.

FOX FORDYCE DISEASE

To the Editor—A youth aged 19 years of Swedish parents has Fox Fordyce disease involving the axillae, the areolar border of the nipples and the pubic area. Treatment has consisted of local applications of ammoniated mercury, Lassar's paste, anthralin sulfur and salicylic acid ointment and Supertab (a proprietary white coal tar ointment). No apparent benefit has resulted and the patient was referred to two dermatologists. One made a diagnosis of chronic folliculitis and the other concurred in my diagnosis of Fox Fordyce disease. Both recommended x-ray therapy. The patient has had about a dozen applications of x-rays without any appreciable benefit. This condition has persisted now for over six years and has received energetic treatment of many kinds. The urine has been negative on repeated examinations. Have you any suggestions as to treatment?
M D Connecticut

ANSWER—The occurrence of Fox Fordyce disease, a rare, chronic, papular disease of the axillae, pubes, breasts and genital and perianal region is unusual in the male, though not so rarely seen as was thought when the disease was first described. It is connected in some way with the apocrine sweat glands, which occur in all these regions in the female but are supposed to occur in the male only in the axillary, pubic and perianal regions. The occurrence about the nipples in the case described is interesting and exceptional. The failure of treatment to relieve the intense itching is typical. Since x-rays have failed to give relief phenol diluted with water, alcohol or glycerin may be painted on, or even 95 per cent phenol used on one small area at a time. If this fails, the injection of 95 per cent alcohol may be tried. Under general anesthesia, the hypodermic needle is plunged vertically into the skin to the subcutis layer and 2 or 3 minims of 95 per cent alcohol injected. The next injection should be about one-fourth inch from the first. The whole area is thus treated, injection into blood vessels being avoided. No dressing is needed. It may be necessary to repeat this treatment after some months.

A salt of ethyl aminobenzoate dissolved in almond oil may be used without preliminary anesthesia. The injections are

made as described for alcohol and the relief is immediate, but it is usually necessary to repeat the injections every few days to get a lasting effect. The itching is usually relieved for several months. This applies to pruritus ani, for which the method was devised, but the same effect should be obtainable in Fox Fordyce disease (Andrews, G C. *Diseases of the Skin*, Philadelphia, W B Saunders Company, 1930, p 367).

Excision of the involved areas has been recommended if all other measures fail.

ARTHRITIS SUBSIDING DURING PREGNANCY

To the Editor—A woman aged 38, with polyarticular arthritis for the past ten or twelve years is entirely free from symptoms during pregnancy. She has had nine pregnancies with return of the trouble between the termination of each labor and the next pregnancy. There is a definite aggravation of symptoms during the menstrual period. She is somewhat overweight and has a tachycardia but physical examination is otherwise essentially negative.
M D Illinois

ANSWER—This interesting remission of arthritic symptoms during pregnancy has not been noted in the literature of chronic arthritis. Some relationship between the joint symptoms and the amount of estrogen in the blood stream seems possible. The trial of one of the estrogenic substances would be of interest and of possible benefit.

There are reports in the literature of instances of idiopathic intermittent hydrarthrosis in which the joint swelling has receded during pregnancy to return after delivery. Ergotamine tartrate is said to have been of benefit. The cautious trial of this drug is suggested, but prolonged administration of this drug is not advisable, owing to the danger of ergotism.

EFFECT OF INJURY ON PELVIC TUMORS

To the Editor—If a person has a tumor or mass within the pelvis and receives a blow or is injured by a fall that brings about an acute inflammation of the tissues within that area and pain and soreness of the parts involved would ultraviolet short wave or zolite treatments be helpful in reducing the inflammation and other symptoms in such conditions? If there is a tumor would the injury cause it to increase in size more rapidly than before?
M D, Nebraska

ANSWER—It is rare for a blow or a fall to bring about an acute inflammation of a tumor and the tissue around it. However, when this occurs, the treatment mentioned should prove as helpful for this type of inflammation as for any other. Unless the injury produces hemorrhage or a twist of the tumor with subsequent obstruction of the blood vessels and edema, there will usually be no striking increase in the size of the tumor.

PHENOBARBITAL ADDICTION

To the Editor—What is a proper dose of phenobarbital as a hypnotic to be used habitually in insomnia? May the desired effect usually be obtained by administering divided doses in the course of the night? How large a dose is likely to produce injurious results and what are those results?
M D California

ANSWER—There is no such dose as the "proper dose for the habitual use" of any hypnotic. Such use is decidedly improper, and, no matter what dose is sufficient at first to induce sleep, habituation would require progressive increase in dosage unless the cause of the insomnia has in the meantime been removed. It is generally better to administer an adequate dose, e g, 0.1 Gm, of phenobarbital at one time than divided doses at intervals. Addiction is fairly readily acquired and when given in excess of from 0.3 to 0.5 Gm is likely to lead to chronic poisoning with symptoms of confusion, mild dementia, debility, ataxia, gastro intestinal disturbance and anemia.

REMOVAL OF HAIR ON NIPPLES

To the Editor—What method of treatment may be followed in removing hair about the nipples in a woman aged 25?
M D Ohio

ANSWER—Electrolysis is the only approved method for permanent removal of hair. A platinum needle attached to the negative pole of a galvanic circuit is inserted into the follicle as deeply as the root of the hair and a current of from 1 to 1.25 milliamperes is allowed to pass for from ten to twenty seconds. Then the circuit is broken and the needle removed and the hair should slip out easily. If the hair is still firmly fixed in the skin, it is probable that the needle did not follow the follicle accurately and the procedure must be repeated. In a second trial fails this hair had best be left until another time. It is important not to treat hairs less than 0.5 cm apart, for fear of scarring. After the treatment a small papule forms, but in a few days it subsides and it is then permissible to give another treatment in this area. For fine hairs a smaller current will suffice.

Book Notices

The Management of Obstetric Difficulties By Paul Titus M.D. Obstetrician and Gynecologist to the St Margaret Memorial Hospital Pittsburgh. Cloth Price \$8.50 Pp 879 with 314 Illustrations St Louis C V Mosby Company 1937

Practically constructed and uncomplicatedly put forth, this volume should prove to be a valuable addition to the library of every physician who does obstetrics. Straightforward in its presentation, there is no great amount of unnecessary detail, the idea of the author being, apparently, to present a practical book for reference. Although the work may be too advanced and lacking in detail to make it valuable as a textbook for undergraduate students, it should make a good reference book for even the student. The book is well written, interesting and easy to read and is profusely illustrated with well done and informative drawings and color plates. Particularly gratifying is the thoroughness of the treatments discussed, both medical and surgical. Rarely does one find this type of book giving detailed treatment, a thing for which the busy practitioner who is seeking information will be thankful. The prescriptions alone should make the book worth owning. For those who are interested in the operative obstetric fields the book is of value because not only does Titus tell one what operation should be done but he goes into some detail in the description of the operative technique. It is difficult to point out particular chapters in the work that merit special attention. The chapter on sterility is excellent in its completeness. Other parts of special note are the chapters on anesthesia and analgesia, the toxemias, cesarean section and the final chapters on intravenous therapy, which is of particular interest and value. The volume by Titus can be highly recommended for addition to the library of any physician who is doing obstetric work.

What Is Osteopathy? By Charles Hill M.A. M.D. DPH Deputy Medical Secretary of the British Medical Association and H. A. Clegg M.A. M.B. MRCP Deputy Editor of the British Medical Journal. With a preface by H. G. Wells. Paper Price 7s 6p Pp 212 with 11 Illustrations London J. N. Dent & Sons Ltd 1937

"Osteopaths are not necromancers they do not invoke the assistance of the planets to guide their deliberations, they have not invented some elixir of life. They have a theory and a practice, and it is the purpose of this book to examine this theory and practice. It is not our aim to persuade patients not to seek the advice of a practitioner of osteopathy. But if a person wants to be treated by an osteopath he should have some idea of what the osteopath can do for him, as he should have some idea of what the ordinary doctor can do for him. So—What is Osteopathy?"

The answer to this question based on the proceedings before the Select Committee of the House of Lords appointed to consider the Registration and Regulation of Osteopaths, cannot be read by any one who has ever spent much time at hearings before legislative committees in the United States without being deeply impressed with the vast difference both in spirit and in method between the British lawmaking machinery and our own. The Select Committee, in a considerable number of hearings, devoted sufficient time to the consideration of this measure to allow the presentation of all pertinent evidence. The British Medical Association was represented by counsel, who was permitted to cross examine the witnesses introduced by the proponents of the bill. In our legislative halls, on the contrary, a couple of hours would be allotted for a hearing and, after the cult advocates had overrun their time, the medical profession would be given the remainder, with questioning of witnesses strictly barred.

The evidence presented to the House of Lords committee may be considered under two heads that dealing with ideas promulgated by Andrew Taylor Still, founder of osteopathy, and that showing how far his modern disciples have departed from his teachings. The cardinal doctrines of Still were the self sufficiency of the body and the unlimited restorative power of nature, the removal by manipulation of mechanical interference with the functions of blood vessels and nerves, the uselessness and harmfulness of all drugs and the entire independence of osteopathy as a system applicable to, and sufficient for, all diseases. The leading advocates of osteopathy who

appeared in support of the bill testified, nevertheless, that they no longer adhere to the principles enunciated by the founder but follow the example of medical practitioners in the use of drugs, serums and surgery. Further it was admitted that no scientific experimental evidence in support of osteopathy had ever been produced. Chapters dealing with osteopathic education in the United States and Britain reveal how far it falls below the standard of schools of medicine. In its report the committee said:

The Committee find on the evidence before them that the claim of the Osteopaths to treat all diseases as set out in the Bill has not been established and that it would not be safe or proper for Parliament to recognize osteopathic practitioners as qualified on a similar footing to that of registered medical practitioners to diagnose and treat all human complaints.

To all who wish to learn something about osteopathy, this book is commended without reserve.

Research Memorandum on Social Aspects of Relief Policies in the Depression By R. Clyde White Professor of Social Economics School of Social Service Administration University of Chicago and Mary K. White Statistician Chicago Council of Social Agencies. Prepared under the direction of the Committee on Studies in Social Aspects of the Depression with the cooperation of the Committee on Social Security. Bulletin 38. Paper Price \$1 Pp 173 New York Social Science Research Council 1937

Research Memorandum on Social Work in the Depression By T. Stuart Chaplin Chairman Department of Sociology University of Minnesota and Stuart A. Queen Chairman Department of Sociology and Anthropology Washington University. Prepared under the direction of the Committee on Studies in Social Aspects of the Depression. Bulletin 39. Paper Price \$1 Pp 134 New York Social Science Research Council 1937

The Social Science Research Council, composed of representatives chosen from seven constituent organizations dealing with the social sciences, has fostered a series of "Studies in the Social Aspects of the Depression," of which these two works are a part. They are devoted to suggestions for lines of research in the subjects considered. They raise a multitude of searching questions, most of which the authors admit are easier to ask than to answer. The objective sought is clearly research that will determine just what has happened to social work and been accomplished by it, and what future tendencies are, with their effect on individuals, society and the social workers themselves. The indefiniteness of the whole field is emphasized by the frequently repeated demand for a determination of objectives.

Both works show the sort of "inbreeding" that is characteristic of social workers. The "Research Memorandum on Social Work in the Depression," while discussing medical relief under the FERA, makes almost no reference to the great amount of published material by medical associations or of the part they played in the organization of that work. In the discussion of medical-social workers there is scarcely any reference to the medical profession, hospitals or the public health service. The bibliographies and footnotes, which are an integral part of a work designed for the guidance of research workers, show the same defects, even governmental documents in these special fields are seldom mentioned. There are so many suggestions of practical outlines for research that it seems safe to predict a great increase in the number of master's and doctor's theses that will follow. The research worker will find these works of great value in outlining the technique to be used in the field of social research. This is especially true of the final chapter of the 'Research Memorandum on Social Work in the Depression.'

Quelques vérités premières (ou soi disant telles) en chirurgie abdominale Par H. Mondor professeur agrégé de pathologie chirurgicale à la Faculté de médecine de Paris. Collection publiée sous la direction de MM. L. Ombredanne et V. Flessinger. Boords. Price 24 francs Pp 97 Paris Masson & Cie 1937

Under the editorial supervision of Drs. Louis Ombredanne and Noël Flessinger have been or are being published a number of short, concise monographs dealing with surgical or medical specialties. It is somewhat difficult to classify such publications, they are not quiz compends nor are they synopses or syllabi. Perhaps "surgical tabloid" comes nearest the truth. Mondor's opus is replete with aphorisms many of which have stood the test of time, while others may or will have to be changed as new truths become revealed. Ombredanne himself suggests that

it might have been wiser to entitle the monograph "truths of today." The field covered includes abdominal wall traumas, gastric, duodenal and pancreatic lesions, intestine and peritoneum, and gynecologic surgery. Writing of abdominal wall trauma, one is advised to reexamine the patient every half hour for possible internal lesions. Abdominal rigidity is considered pathognomonic of a lesion of the hollow viscera. To give morphine to a patient with a lesion of the abdominal wall of unknown severity is clumsily to mask symptoms which are anxious to unfold themselves. In the presence of gastric cancer with metastases, one should always perform a gastro-enterostomy, it may palliate for a long time. In cases of chronic pancreatitis with enlargement and hardening of the head of the pancreas, drainage of the common duct is advocated. In milder cases (formes frustes), cholecystostomy and prolonged drainage are preferred. In rectal cancer the surgeon is only too often consulted two years after the onset of symptoms, one year after the first consultation. Rectal examinations should be made more frequently. Three laboratory tests, added to a pelvic examination, should confirm the presence of an ectopic gestation, namely, the Aschheim-Zondek reaction, which is of prime importance, and red and white blood counts. Pelvipеритонitis, when not puerperal or postabortive, is almost always due to the gonococcus. Examination of the vulvovaginal secretions should confirm the diagnosis. Surgical intervention in such cases is a grave error. In acute peritonitis one is justified in making use of the x-rays in order to diagnose a possible pneumoperitoneum, provided too much valuable time is not spent in so doing. If x-ray examination is negative but the clinical signs point to perforation, one should operate at once.

These are only a few of the trite statements to be found throughout the monograph. As a refresher, it should prove of value to the average surgeon, it is too dogmatic for students preparing their examinations. As a compendium of generally accepted facts, there is little to criticize and much to commend.

Surveys of American Higher Education. By Walter Crosby Eells. Professor of Education, Stanford University. Paper. Pp. 538 with 11 illustrations. New York City: Carnegie Foundation for the Advancement of Teaching, 1937.

Under the sponsorship of the Carnegie Foundation, Professor Eells of Stanford has made a critical study of the records of surveys in the field of higher education in the United States. Beginning with the Oberlin study in 1908, more than 500 such surveys were identified. Printed and published reports to the number of 230 constitute, however, the primary basis of Professor Eells' analysis. Particular attention has been paid to the technique of educational surveys and to the methods of presenting the data obtained. An interesting chapter has been devoted to an attempt to appraise the results of surveys as seen by the institutions affected and others. Thirty, regarded as outstanding, have been subjected to detailed analysis. The appendices contain a wealth of material on such subjects as surveying agencies, costs and financing of surveys, bibliography, and opinions concerning future trends in higher educational surveying. Like the war to end war, this survey of surveys is not final. On the one hand, some significant material has been omitted, and, on the other, new plans and procedures have been developed since Professor Eells collected his material.

Diseases of the Nervous System in Infancy, Childhood and Adolescence. By Frank R. Ford, M.D., Associate Professor of Neurology, The Johns Hopkins University. Cloth. Price \$8.50. Pp. 953 with 107 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1937.

This book is a timely contribution to the field of neurology in infancy and childhood. Besides the subjects of strictly neurologic interest the author has included neurologic complications of general diseases, so that it is encyclopedic in scope. In the first part the examination of the nervous system and clinical aspects of the anatomy and physiology of the nervous system are concisely handled. Only essential data are presented and at the end of each discussion is a well selected bibliographic reference by which the reader may extend his interest. Most of the references given are those which are written in English. The succeeding chapters deal with neurologic disturbances classified on the basis of etiology and presented in a manner that stresses the clinical features of the disorders. These embrace such subjects as prenatal diseases of the nervous sys-

tem, hereditary and degenerative diseases of the nervous system, infections and parasitic invasions of the nervous system, toxic and metabolic disorders involving the nervous system, vascular and circulatory disorders, neoplasms, injuries by physical agents, the epilepsies and paroxysmal disorders of the nervous system, diseases of the autonomic system, myopathies, and finally a discussion of syndromes and symptom groups. In spite of this scope the author does not present anything that is not useful and essential. The material is well organized and carefully edited. It is adequately illustrated and the written material is presented in a readable style. A vast amount of data is handled scholarly in one textbook that ordinarily would be found in several volumes. The book should appeal to the general practitioner as well as to the pediatrician and neurologist. Every medical library should have a copy, as it will serve as a valuable reference work on the subject of pediatric neurology.

A Textbook of the Practice of Medicine. By Various Authors. Edited by Frederick W. Price, M.D., C.M., F.R.C.P., Consulting Physician to the Royal Northern Hospital, London. Fifth edition. Cloth. Price \$12.50. Pp. 2638 with 112 illustrations. New York & London: Oxford University Press, 1937.

The first edition of this textbook appeared in 1922 and each edition since has had from one to four additional impressions. The contributors are well chosen and not so numerous as usual in American books of the same cooperative type. This fact adds, perhaps, to the evenness of presentation. There have been some alterations in classification which demonstrate the change in our views of certain diseases. Thus herpes zoster has been transferred from the diseases of the skin to the sub-section on diseases due to filtrable viruses, hysteria and neurasthenia have been withdrawn from the section on the nervous system and placed in that on psychologic medicine. In the index, which is exceptionally good (153 pages for 1,883 pages of text) reference to prontosil for streptococcal infections is found, while on the page referred to prontosil is not mentioned but there is a brief reference to "sulphonamide." It might be pointed out that many of the electrocardiograms could be improved on so far as reproduction is concerned. It is noted also that under treatment of gonococcal arthritis no mention is made of hyperpyrexia, which, at least up to the time of sulfanilamide, was the most promising form of therapy. Too much criticism of this book, however, would be invidious, since it is well written, exceptionally complete, and easily used as either a textbook or a reference book.

The Spectacle of a Man. By John Colquhoun. Cloth. Price, \$2.50. Pp. 252. New York: Jefferson House (William Morrow & Co., Inc.), 1937.

This is a novel about a man whose excessive, pathologic shyness, increased by stuttering and stammering since childhood, made it impossible for him to establish any satisfactory relationships with men and women, resulting in almost complete withdrawal from normal social intercourse and a sense of great inferiority and unhappiness. The author shows how, through psychoanalytic therapy, the patient is freed from the tyrannical domination of his unconscious infantile emotions and cravings and in consequence is able to live a freer and fuller affective life. In working out the psychodynamics, the *oedipus* situation in its simplest and most classic form is utilized. Only a relatively small part of the book occupies itself with the actual analysis. By far the largest portion is devoted to a description of the patient's actual life during the analytic months. Writing for the intelligent lay reader, the author has wisely refrained from the use of technical terminology and involved psychologic interpretations. In simple language, without resorting to sensational and melodramatic situations, he works out the psychodynamics in a sufficiently valid and convincing manner. He does not pretend to describe an orthodox or scientifically correct analysis and almost entirely neglects except for brief references, the transference situation. These technical deviations, including the use of a diary during analysis, in no way detract from the value of the book, the purpose of which is manifestly to give a nonclinical description of a neurosis and its treatment, in novel form for the lay reader. Many passages, devoted to intellectual psychologizing, are somewhat dull and slow and could probably be condensed.

Disease and the Man By Roger F. Lapham A.B. M.D. Cloth Price \$9 Pp 143 New York Oxford University Press 1937

We are accustomed to hearing the older generation of physicians lament the passing of the "art" of medicine and deplore the increasing dependence on indirect methods of examination with consequent failure to cultivate the senses by painstaking direct examination. Too often, we have been told, anamnesis is supplanted by a laboratory report. In the book under review a similar thesis is challengingly presented by one of our younger physicians, who has completed comparatively recently his medical course and hospital training. Dr. Lapham so forcefully presents the paramount importance of the patient and of the personal relationship of the doctor that his title might well have been transposed "The Man and the Disease." In an early chapter the spirit of the true physician is accurately portrayed. History taking and the physical examination are vividly described with illustrative cases to demonstrate their significance. Suggestions for the follow up and for controlling patients are similarly reinforced and enlivened by circumstantial anecdotes drawn from his own experience. Two illuminating chapters deal with that ever present problem the neurotic patient. Dr. Lapham concludes with the statement "it is the sincere hope of the author that a consideration of this discourse may help us to recognize the practice of medicine as a problem which embraces infinitely more than just a cold science of treating disease." No recent work so deftly discloses the man who must be treated rather than abstract pathology.

Quelques vérités premières (ou soi disant telles) en oto-rhino-laryngologie Par Marcel Ombredanne oto-rhino-laryngologiste des hôpitaux de Paris. Collection publiée sous la direction de MM. L. Ombredanne et A. Fleissinger. Boards. Price 24 francs Pp 86 Paris Masson & Cie 1937

In his preface the author states that, while there are many disputable conceptions regarding theories of pathogenesis, some clinical facts and some therapeutic results seem to be definitely settled. In this little brochure Ombredanne considers important points relative to the nose, nasal sinuses, larynx, trachea, esophagus and ear as well as the various methods of examination, such as bronchoscopy, covering them in the course of eight chapters. The discussions under various headings and sub-headings are in the nature of short statements resembling aphorisms. Attention is called to only the most important facts, and many epigrammatic statements refer to various essential facts, such as the warning with regard to the danger of infection at the entrance of the nose or upper lip and the possibility of extension by way of septic thrombophlebitis to the interior of the cranium and the consequent septicemia and death. The author warns against manipulation of the furuncle which is the primary lesion. This little book is valuable to the otolaryngologist but one must remember that oversimplification is not suitable for those who have not already thoroughly mastered the principles of the specialty and have had a reasonable degree of practical experience. This brochure is written and the subject is presented in the clear, concise manner so characteristic of good French writers. It will well repay the practicing otolaryngologist and especially the teacher of this subject to refer frequently to this work.

Accepted Dental Remedies Containing a List of Official Drugs Selected to Promote a Rational Dental Materia Medica and Descriptions of Acceptable Nonofficial Articles 1937. Edited by Samuel M. Gordon Ph.D. Secretary Council on Dental Therapeutics. Cloth Price \$1 Pp 265 Chicago American Dental Association 1937

This is the first revision published in two years of the list of pharmaceutical articles that have been accepted by the Council on Dental Therapeutics. The list has been thoroughly revised and the information on the official drugs brought in line with the recently published eleventh edition of the U. S. Pharmacopeia and the sixth edition of the National Formulary. The 1937 edition reflects the position of the Council on Dental Therapeutics on the abrasiveness of dentifrices and gives for each dentifrice listed as acceptable, statement of its composition and of the source and kind of insoluble materials in it and of the abrasiveness of the finished dentifrice. Special mention is made of the revisions of the chapters on calcium compounds, epinephrine cod liver oil, opium derivatives local anesthetics and atropine preparations. The plan of this book follows the

plan of two publications of the Council on Pharmacy and Chemistry of the American Medical Association—Useful Drugs and New and Nonofficial Remedies—and credit is given to the Council on Pharmacy and Chemistry for material from its publications which have been adapted in this book to the needs of dentists.

A Textbook of Surgical Nursing By Henry S. Brookes Jr. M.D. Instructor in Clinical Surgery Washington University School of Medicine St. Louis. Cloth Price \$3.50 Pp 636 with 233 illustrations. St. Louis C. V. Mosby Company 1937

If it were not for the three chapters pertaining to the duties of the operating room nurses, the various surgical procedures nurses should know and the diets for surgical patients, the remaining twenty-eight chapters might well be called an abbreviated textbook of surgery. This purpose the book fulfills with unusual completeness. It covers general and special surgery briefly but accurately, including the genito-urinary system and gynecologic surgery as well as the surgery of bones and joints. The book is well written in a clear simple style. It is excellently and abundantly illustrated. With a change of title to Textbook of Surgery for Nurses, it may well be recommended for the purpose intended.

Diabète et chirurgie Par H. Chabanier et C. Lobo Onell. Avec la collaboration de Mlle E. Lellu. Préface du Dr. M. Robinet. Paper Price 22 francs Pp 168 Paris Masson & Cie 1936

This is probably the most extensive clinical and laboratory treatise dealing with all the medical phases that come up in the control of a diabetic state before and during surgery. The underlying theme of the treatment is saline solution from 10 to 20 Gm. insulin and dextrose intravenously. The point in which this differs from the American publications is the stress which the authors lay on the administration of salt in hypertonic solutions. Their experiments as well as their clinical data sound convincing. The authors cover the world literature and the book is well worth while for those who have to deal with surgery and diabetes. The author has paid close attention to detail, which is the criterion of his successful therapy.

Textbook of General Physiology By T. Cunliffe Barnes D.Sc. Assistant Professor of Biology Yale University. Cloth Price \$4.50 Pp 554 with 166 illustrations. Philadelphia P. Blakiston's Son & Co. Inc. 1937

Barnes has given a new and fresh point of view in general physiology. Since the publication of Bayliss's Principles of General Physiology, this is the first book in English to give a significantly improved approach. The author himself is a prolific contributor to the field of general physiology, especially in the fundamental problems of water metabolism, and his chapters on physical chemistry applied to physiology are especially valuable. Of 477 pages, 267 are devoted to such topics. There has not been a more intelligent or more comprehensive biologic treatment of these questions in any language. There is a large and valuable bibliography, and the book is well indexed. The illustrations are ingenious and many, particularly the diagrammatic ones, are original.

Unreife und Lebensschwäche Von Prof. Dr. Albrecht Pelpel. Boards Price 6.80 marks Pp 103 with 10 illustrations. Leipzig Georg Thieme 1937

This monograph concerns itself with the physiologic and clinical aspects of prematurity and immaturity. The author believes that the conventional boundary of maturity, 2,500 Gm. birth weight, is too high and should be 2,000 Gm. He then discusses the incidence of and basis for prematurity and immaturity. Growth, body chemistry and metabolism are next discussed and differences between the mature infant are discussed. Then follow concise discussions on hormones, ferments, nutrition, circulation and respiration. Clinical disorders associated with prematurity and immaturity are then discussed. The concluding discussion concerns itself with the management and care of the premature. The monograph is concise but covers the subject comprehensively. Few original data are found in the work, but the author handles his material well. The bibliography is extensive but is confined almost entirely to European literature. The book has merit as a terse but comprehensive summary of physiologic and clinical aspects of prematurity and immaturity.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Death from Malignant Endocarditis in Relation to Industrial Injury—In the course of his employment on March 9, the workman fell down a stairway, apparently hitting his right hip. Two or three hours later he was forced to quit work. The day after the accident his attending physician found him suffering pain in the pelvic region. After remaining at home for five days, the workman returned to work a few days but eventually had to cease his employment altogether. The attending physician was called again May 9 and found the patient suffering from "terrific chills and fever," and subsequently a diagnosis of "generalized septicemia undoubtedly from a heart lesion" was made. The workman was hospitalized and given five or six transfusions. He died June 30 from "malignant endocarditis with generalized septicemia." The workman's compensation commission of Utah denied his widow compensation and she appealed to the Supreme Court of Utah.

The attending physician first testified that he could see no connection between the accident and the death. Later on, however, he testified that "we know he had septicemia and we know he had a very pronounced mitral insufficiency," that a fall could have "jarred loose some of the bacteria on the heart valves and thrown them loose in the blood stream," and that the industrial accident could have therefore been a contributing factor in the death. If the workman had not had a fall, this witness testified, he would not have died at the time he did. The testimony in this case, said the Supreme Court, certainly would have supported an award in favor of the widow, in fact, it seemed to show rather decidedly that the fall aggravated a preexisting condition. Yet it was for the industrial commission to decide the relationship between the accident and the death. There was only one physician who testified and he gave conflicting opinions. He thus evidenced uncertainty as to the real cause of death. Under such circumstances, in the opinion of the court, the finding of the commission was not arbitrary. The order of the commission denying compensation was affirmed.—*Holbrook v Industrial Commission (Utah)*, 67 P (2d) 224

Right of a Physician to Refuse to Testify Unless Paid a Special Fee—One Lillian Taves sued the Safeway Cab Transport & Storage Company to recover damages for personal injuries. Prior to the trial, at the instance and request of the company, Dr Opie W Swope, a physician specializing in radiology, took some roentgenograms of her injured arm. On the morning of the day of trial, the husband of the injured woman called on Dr Swope for the purpose of getting him to testify for his wife. Dr Swope agreed to do so on condition that his appearance as a witness would be satisfactory to the company that had employed him to take the roentgenograms and on condition that he be paid the customary expert witness fee of \$25, to be paid when he arrived at the courtroom. Apparently the stipulation with respect to the fee was agreed to. In any event Dr Swope appeared at the trial in answer to a subpoena duces tecum, bringing the roentgenograms with him. The special fee, however, was not paid and Dr Swope refused to testify. The court directed him to take the witness stand, which he did under protest. He was asked to produce the roentgenograms and he refused. He likewise refused to testify unless his special fee was paid. The court thereupon found him guilty of contempt of court, fined him, and ordered him committed to jail until the fine was paid. Dr Swope instituted proceedings for a writ of habeas corpus and when his application for the writ was denied, he appealed to the Supreme Court of Kansas.

The question, said the Supreme Court, whether an expert witness may be compelled to testify if special compensation has not been paid him has been considered in many cases. In

some of the states there are statutory provisions which permit the trial court to fix such compensation. There is no such statute in Kansas. The general rule as to compelling an expert witness to testify is stated in 70 C J 75, as follows:

The more general rule is that, apart from statute, an expert witness may be compelled to testify as to matters of a professional opinion, or matters to which he has gained a special knowledge by reason of his professional training or experience, without any compensation other than the fee of an ordinary witness, and his refusal to testify unless paid an extra compensation may be punished as contempt.

The present case, the court said, does not present a situation where the witness, at the suggestion of the party calling him, did anything by way of preparation to testify, neither does it present any situation where there was any attempt to compel him by any order of the court to prepare himself to testify. The professional services of the witness were rendered at the request and cost of a person other than the one calling him to testify. It was contended that Dr Swope refused to produce the roentgenograms which the subpoena had compelled him to bring because he anticipated that he would be asked to express his professional opinion based on them. Assuming that to be true, the court said, Dr Swope was not warranted in refusing to produce the roentgenograms, nor would he have been warranted in refusing to answer questions based thereon.

There are experts of many kinds, professional as well as lay. Many men are experts in certain lines of endeavor. If physicians, dentists, lawyers and engineers may refuse to testify concerning matters on which they may have opinions due to their respective trainings, simply because special fees have not been paid them, then a person qualifying as an expert shoe repairer may not be compelled to state what was the matter with shoes he repaired unless a special fee is paid him. It can readily be seen, the court said, that such a situation would be intolerable. It would tend to permit those who could afford it to produce witnesses whose testimony might be said to be expert and would prevent those without requisite means of the benefit of such testimony. We are not referring, the court said, to that class of cases where special preparation is required as a condition precedent to testifying but to those where the witness is interrogated as to facts and opinions which he knows and has without such special preparation. In the absence of a statute authorizing the trial court to fix expert witness fees, or permitting the witness to refuse to testify until a stipulated fee has been paid, the court was not disposed to hold that a witness claiming to be an expert called on to give expert testimony may refuse to testify unless his demands have been met.

The court concluded, therefore, that the witness was not justified in his refusal to produce the roentgenograms and to testify and the judgment of the trial court denying the application for a writ of habeas corpus was affirmed.—*Swope v State (Kan)*, 67 P (2d) 416

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Serum Phosphatase in Bone Disease—Woodard and Higinbotham determined the serum phosphatase by the Bodansky method in 203 persons with normal, benign and malignant conditions of the bone. Their estimations appear to warrant the following conclusions: 1 If a high serum phosphatase is found associated with an osteoplastic lesion or a normal serum phosphatase with an osteolytic lesion, the phosphatase determination has served only to confirm the diagnosis made by roentgenogram. 2 If a normal serum phosphatase is found associated with an osteoplastic lesion, the process is probably slow growing and relatively benign. 3 If a high serum phosphatase is found associated with an osteolytic lesion, the case may be one of hyperparathyroidism, there may be osteoplastic disease elsewhere in the body, the case may be one of a group made up chiefly of endotheliomas or carcinomas of diverse origin, metastatic to bone which raise the serum phosphatase level, but for some unknown reason do not form new bone, or the case may be an early highly malignant osteogenic sarcoma. 4 Follow-up determinations of the serum phosphatase in cases with an initially elevated phosphatase may predict the development of metastases after the extirpation of the primary tumor but cannot be depended on to do so. 5 Determinations of serum phosphatase in cases of bone tumors which have been treated by roentgen or gamma rays are useful in indicating the degree and permanence of the inactivation caused by irradiation. 6 While the presence of a normal serum phosphatase gives no assurance that disease of the bone is absent, the presence of a persistently elevated

serum phosphatase in a patient who is not jaundiced and who is not under treatment with Coley's toxins is a strong indication that disease of the bone is present and should never be disregarded.

Hypoglycemia—Martin and Hellmuth reviewed the available histories of patients in the Johns Hopkins Hospital in whom hypoglycemia was discovered. The blood sugar in 341 patients, uninfluenced by injection of insulin, was found at some time to be below 70 mg per hundred cubic centimeters, also in sixty-three patients the blood sugar was in the seventies. Hypoglycemia has been found to be associated with a large number of pathologic conditions. In these conditions symptomatic pathognomonic of hypoglycemia were found in 89 per cent of the cases and suggestive symptoms were present in 20 per cent. In patients with symptomatic functional hypoglycemia, symptoms may appear at a higher level of blood sugar than in patients with a recognizable basis for their hypoglycemia. Except for the cases of symptomatic functional hypoglycemia and of epilepsy there are relatively few other instances in which patients with definite symptoms of hypoglycemia had no recognizable basis for their hypoglycemia. A number of laboratory and clinical data could not be correlated with hypoglycemia. There are individuals with symptoms of hypoglycemia of unexplained etiology whose diagnosis should be 'symptomatic functional hypoglycemia'. Many individuals become accustomed to or do not react to a lowered blood sugar that would produce symptoms in others, as in hypoglycemia arising from an organic basis. A lowered blood sugar concentration should not be accepted as a cause of that vague symptom complex which is especially typified by the psychoneurotic individual.

X-Ray Diagnosability of Military Tuberculosis—Steiner made a study of the correlation between the histologic structure of military tubercles and their x-ray diagnosability during life and compared the importance of the histologic make-up with the factors of the size and the number of tubercles in producing shadows. An effort was made to keep the study as objective as possible by using actual measurements

and by submitting data to statistical analysis whenever possible. Fifteen cases of generalized milary tuberculosis examined post mortem by various members of the department of pathology of the University of Chicago and thirty-one cases examined by pathologists at the Children's Memorial Hospital of Chicago were studied. A comparison of the roentgenograms with the number, the average size and the histologic structure of the tubercles in the lungs revealed the latter factor to show the best correlation with the x-ray appearance. The antemortem roentgenograms were negative in all cases in which the tubercles were epithelioid, whereas, in cases with tubercles containing caseous material or collagen or both, the roentgenograms were usually positive. The chemical explanation for this observation is not known. None of the tubercles contained visible calcium on the routine stains and micro-incineration of tubercles of the various histologic types revealed no significant quantitative difference in the ash. By using softer x-rays or by selective filtration of x-rays of certain wavelengths, epithelioid tubercles might produce positive roentgenograms.

Weil's Disease.—Gaines and Johnson review the pertinent literature on Weil's disease and describe the important symptoms in the thirteen cases reported previously in North America and of their series of seven cases. The relationship of Weil's disease to infectious jaundice is discussed. The diagnosis and treatment are considered, with particular attention to their results of treatment with neosarsphenamine intravenously and convalescent whole blood and serum intramuscularly. The most unusual feature was the typical painless obstructive jaundice of eight months' duration noted in the second patient at the time of his admission to the hospital. Operation and necropsy in this case revealed complete inflammatory atresia of the intramural portion of the common bile duct secondary, presumably, to Weil's disease. The third patient showed an afebrile course, and leptospirae were demonstrable in the blood by dark-field examination for nine weeks. The fourth patient also was afebrile throughout, and leptospirae were demonstrable for five weeks. The fifth patient appears to be the only woman with Weil's disease in the North American literature, except in one instance of accidental laboratory infection. The seventh patient showed an afebrile course and was ambulatory for a period of eight months before the diagnosis was made, cholecystectomy was performed during this period without benefit. Six of these cases were diagnosed during a period of six months, indicating that this condition may not be rare. The disease should be considered more often when there is unexplained jaundice.

Arsenical Poisoning During Treatment of Leukemia.—Kandel and LeRoy describe a case of chronic myeloid leukemia in which intensive treatment with solution of potassium arsenite and x-rays was given and in which cutaneous and

hepatic lesions due to the arsenic developed. The results of arsenic therapy of five other patients with chronic myeloid leukemia who showed certain features of this form of treatment are included. Five of the six patients presented at one time or another in the course of treatment complications (herpes zoster, cirrhosis, keratosis, polyneuritis, erythema, portal fibrosis and ascites) known to result from arsenic. All these patients after taking the drug for longer than five or six months complained of a chronic cough, and examination of the chest frequently disclosed moist rales. Since many patients readily tolerate enough arsenic to produce these complications without suffering unduly from the minor so-called subtoxic symptoms of conjunctival and nasal congestion and gastrointestinal disorders, the therapeutic principle is obvious. A patient should not be permitted to dose himself to his idea of tolerance with solution of potassium arsenite over long periods without medical supervision. The possibility that ascites is due to the therapy should be remembered and when it occurs a long rest period, with administration of diuretic drugs, is indicated. If keratosis appears, permanent interdiction of arsenic is not indicated. Rather, the drug should be discontinued until the soreness leaves and then begun again cautiously. If the leukocyte count does not stay at a low level during the rest periods but rises so rapidly that solution of potassium arsenite must be taken almost continuously, roentgen therapy should be given. Arsenic therapy and roentgen therapy are not antagonistic and a remission of leukocytosis may be induced with arsenic as soon as the postirradiation decline of the leukocyte count ceases. Also, years of arsenic medication do not render a patient resistant to roentgen therapy. The employment of the twenty-one day cycle of increasing doses of solution of potassium arsenite, followed by twenty-one days of rest, seems to be the most satisfactory method of giving the drug. With control of the course by making frequent leukocyte counts especially at the onset of treatment, necessary adjustments of the doses are readily made. In cases of typical chronic myeloid leukemia the outlook is best when the hemoglobin and erythrocyte counts can be kept at the highest level. Vigorous effort to attain an approach to normality in this respect is important.

Local Cellular Reaction to Tuberculin.—Feldman and Fitch made a histologic study of the changes in the tissues which follow intracutaneous injection of tuberculin into experimentally sensitized calves. The study included nine calves which were infected with bovine tubercle bacilli and two control calves which were not infected. After the lapse of fifty-eight days, the usual diagnostic dose of mammalian tuberculin was injected into the derma of each caudal fold of each calf. Starting at the third hour after the tuberculin was introduced and continuing at intervals to the twenty-eighth day, portions of the respective caudal folds were removed for biopsy. The essential histologic features were as follows. The reactive process gave evidence of a constant predilection for the perivascular and perineural tissues. During the early phases of the reactive process polymorphonuclear leukocytes were numerous. Eosinophilic granulocytes and histiocytes were in the minority. A histiocytic or mononuclear cellular reaction gradually replaced the polymorphonuclear leukocytes and dominated the picture, beginning at the sixtieth or the seventy-second hour. Edema appeared early in the reaction and disappeared between the fifth and seventh days. Certain endovascular changes including thrombosis and endarteritis occurred. Resolution of the cellular reaction had not occurred after twenty-eight days. The injection of tuberculin into the skin of nonsensitized calves failed to provoke demonstrable changes.

Development of Tar Carcinoma in Mice—Having observed for six years more than 600 mice in which tar carcinoma was produced and inhibited, it seems to Davidson to be fairly well demonstrated that the tumor threshold of the mouse can be lowered by tar irritation and raised or maintained at a fairly constant level by breeding and diet, with varying dosages of vitamins administered in the diet (especially those associated with reproduction A B and C). A distinct difference is observed in the condition of the control groups on the two different vitamin diets. The following information obtainable with the completion of this series on the death of all the experimental mice, will be of help in adjusting vitamin dosage (1) whether the present vitamin dosage of the high vitamin diet will maintain the animal throughout life or will have to be increased with age and (2) to observe and compare the tumor threshold in different groups.

Treatment of Epilepsy in Children—A ketogenic diet producing large amounts of diacetic acid in the urine is a satisfactory method of treating epilepsy, particularly in children. Keith has treated 160 patients satisfactorily over a period of from one to nine years. Of these, 36 per cent remained entirely free from attacks of any type so far as is known to themselves or to their parents. 21 per cent were improved, having only an occasional attack, 43 per cent were not benefited although they carried out instructions fully. Therefore with the ketogenic diet alone one third of the epileptic children can be made free from seizures and from 50 to 60 per cent can be improved. A ketogenic diet, to be effective must be rigidly controlled and should be a weighed diet. It is necessary that in the diet the ratio of the ketogenic material to the antiketogenic be at least 3:1. For children the number of calories is 55 per kilogram, or 25 per pound of body weight. The amount of protein is set at 1 Gm per kilogram of body weight. The carbohydrate and the fat are then adjusted so that the ratio is as indicated and the calories are satisfactory for nutrition and growth. In using diet or medication one must not lose sight of the necessity for healthy outdoor exercise or adequate rest and general hygienic measures. For many years surgeons have attempted to treat epilepsy by different forms of surgical procedures. These methods are perhaps more often carried out in adults than in children. A tumor may produce convulsive attacks, and many tumors may now be removed with satisfactory results. However, first one must study the patient's history, the pattern of the seizures, the neurologic examination and

finally the encephalogram, to determine what area of the brain has been involved. If these all point in the same direction, it is then considered advisable to explore the suspected area of the cerebral cortex with electrical stimulation. If the focus is found as suspected, the area may often be removed with successful results.

Excretion of Androgenic and Estrogenic Substances—To determine the presence of androgenic and estrogenic activity, Dorfman and his co-workers assayed the total excretion of urine, for periods varying between twenty-four and 168 hours, from eighteen boys and five girls from 6 to 16 years of age. Androgenic activity was found in the urine of all the children in amounts varying from 11 to 32 international units for twenty-four hours. The estrogenic activity observed ranged from less than 5 to 95 international units for the same period. The androgenic and estrogenic activities of the urines vary in puberal boys of the same chronological age. Since puberal girls of the same chronological age also differ markedly in the degree of their physical development, one may expect comparable differences in their hormone excretion. These considerations indicate the inadequacy of chronological age alone as a criterion of maturity. They emphasize also the need for caution in interpreting the results of assays of pooled samples of urine from children of the same chronological age, if the latter differ markedly in their developmental status. Because of this variation the assay values for the various age groups in the authors study are not necessarily the same as those which may be found for other children of the same age. Owing to the marked variation in the developmental status of children of the same chronological age the relationship of the excretion of the sex hormone more directly to the degree of physical maturity is being investigated.

 *Blood Bromide Investigations in Psychotic Epileptics L Minski and J B Gillen—p 850
 *Treatment of Obstinate Edema by Multiple Punctures M Sein—p 852

Blood Bromide Investigations in Psychotic Epilepsy—Minski and Gillen estimated the blood bromides of thirty-two chronic epileptic psychotic patients and, although comparatively high levels were found in many cases, no obvious instances of true bromide intoxication showing delirious or confusional reactions were discovered. Reduction in the level of the bromide produced no appreciable change in the mental state and no marked increase in the number of fits, which were definitely reduced in eight cases.

Treatment of Obstinate Edema by Multiple Punctures—Sein believes that the mechanical removal of edema fluid by acupuncture is a useful addition to the therapeutic measures available for the treatment of obstinate edema. The method possesses several advantages over the use of Southey's tubes. The patient having been placed in the most comfortable position, the legs and feet are prepared as for an operation. From fifteen to twenty punctures are made with a triangular skin-needle on the inner aspect of the lower part of the legs and the dorsum of the feet. The needle is placed against the skin and quickly pressed into it, and the point is pushed obliquely upward into the subcutaneous tissue and withdrawn. Veins can be felt and avoided, but bleeding, if it occurs, is easily controlled by a little pressure. Fluid will flow out from the punctures and collect in the receptacle placed under the feet. If the ascites tends to diminish rapidly, it is advisable to apply an abdominal binder as after paracentesis. Light massage of the limbs may be employed to promote drainage and overcome the stiffness of the joints. When it is decided to stop the drainage, all that is necessary is to put the patient to bed and wrap the legs and feet in an absorbent dressing for two or three days while some oozing from the punctures remains.

Some Chronic Nontuberculous Pulmonary Conditions—O'Brien cites some of the clinical and x-ray features of a group of patients suffering from nontuberculous diseases of the lungs. Such features are not rare and interesting, but their incidence should be considered. Three groups of cases are presented: the bronchiectatic, the indeterminate and the neoplastic. In a certain number of these patients the physical signs and general examination could lead to only one diagnosis, namely, pulmonary tuberculosis, but here is stressed the necessity for auxiliary aids to diagnosis in cases of pulmonary disease simulating tuberculosis when the bacillus of tuberculosis is repeatedly absent from the sputum, in "mirror tests" of expired air and in contents of gastric lavage.

Anemia and Agranulocytosis During Sulfanilamide Therapy—During the past two years since the introduction of prontosil, various similar compounds have been employed. Jennings and Southwell-Sander say that it is becoming evident that insufficient warning was given of the possible toxic effects of these drugs. There may occur cerebral disturbances, e.g., drowsiness, dizziness, headache and disorientation. Also described are alimentary symptoms, such as vomiting, the signs of irritation of the urinary tract and signs of peripheral sensory disturbance. An important toxic effect of this group of drugs is shown in the blood picture. Sulfhemoglobinemia and methemoglobinemia are the best known features of this. The authors' report is confined to the toxic effect of the drugs shown by the blood count, which revealed in one of their cases a complete agranulocytosis and in three others some degree of anemia with evidence of abnormal activity of the bone marrow. As is suggested by its chemical structure, *p*-aminobenzenesulfonamide (sulfanilamide, or prontosil album) is a potential marrow poison. The experience of others suggests that the new drugs related to sulfanilamide are likely also to have a similar action on the marrow. Both erythropoiesis and leukopoiesis may be depressed by sulfanilamide, and as is true of other of its compounds, it may act to a different degree on these two functions in the same individual. In considering treatment with these drugs, certain facts must be borne in mind. "Idiosyncrasy" may be present and result in the appearance of symptoms after the administration of a small quantity of the drug. Apart from any such dramatic abnormality in the response, symptoms of toxicity may appear after prolonged or intensive administration; the size of the dose required to cause such symptoms is variable. The general health of the patient may be of importance. The treatment should be guided whenever possible by blood counts. The appearance of immature erythrocytes or a leukopenia is an indication to pause in the therapy. Control of the blood picture is particularly desirable when intense or prolonged therapy (longer than two weeks) is projected.

Effects of Influenza on the Lung—Scadding made a clinical study of the changes in the lungs of fifty-eight patients with influenza admitted to Hammersmith Hospital in December 1936 and January 1937. The influenzal virus was isolated from four of these patients. Twenty-two cases presented abnormal pulmonary physical signs without x-ray evidence of consolidation. In the less severe cases of this group, areas of 'suppressed' breath sounds at the bases were the most distinctive physical signs. The more severe cases presented a clinical picture of edematous bases of the lungs and their gen-

eral aspect resembled that of patients with actual consolidation. Nineteen had actual consolidation. Of these, seven died. The characteristics of the signs of consolidation were extreme dullness to percussion, weak tubular or bronchial breath sounds and egophony. Bacteriologic studies of the sputums showed that the bacterial flora of the series as a whole was no different from that of the noninfluenzal sputums examined during the period of the epidemic. Analysis of the results according to the clinical grouping showed significant differences between the bacterial type distributions in the various groups: pneumococci, which were absent from the sputums of the group without evidence of pulmonary involvement, predominated in the group of those with consolidation. One case of fulminating 'influenzal' pneumonia, fatal on the third day, is described. In the lung both *Staphylococcus aureus*, in enormous numbers, and the virus were demonstrated. The difference between this series and the disease in pandemic times is one of degree rather than of kind. The influenzal virus can produce severe changes in the lung in man which facilitate invasion by bacteria. The course of the disease depends on the extent and virulence both of the virus and of the bacterial infection, the extraordinary variability of the clinical picture is due to the numerous possible combinations of these factors.

Acute Perforated Peptic Ulcer—Chang considers the general data of peptic ulcer as observed at the Peiping Union Medical College and as a survey of the results of treatment. The incidence of peptic ulcer revealed by 2,000 consecutive necropsies was 17 per cent. The ratio between males and females suffering from this condition was 3.3:1. The incidence of perforation among the total number of patients with peptic ulcer admitted was 10.4 per cent, 13.2 per cent among the men and 1.2 per cent among the women. The third decade of life was the age of highest incidence and at least one third of all the perforations occurred before symptoms had been present for more than one year. More than 97 per cent of the perforations were located at or near the pylorus. The time elapsing between perforation and operation was the most important single factor affecting the prognosis. The mortality rose in direct proportion to the lapse of time up to the end of the second day, after which it declined slowly. Diffuse peritonitis, usually streptococcal, constituted the most fatal complication, whereas bronchopneumonia was the most frequent. Simple closure, excision and pyloroplasty, closure and gastro-enterostomy were the chief procedures employed in treatment. None

of these methods yielded strikingly different end results. The author favors simple closure and pyloroplasty in most instances rather than gastro-enterostomy. Primary partial gastrectomy is believed to carry a prohibitive mortality in the hands of the occasional operator, although excellent results have been reported by experienced surgeons. Careful postoperative care and prolonged medical management are essential in all instances. The end results of all types of therapy still leave much to be desired.

Clinical and Experimental Research on Malignant Diphtheria. A. Stroe and D. Hortopan—p. 681

*Large Doses of Strychnine in Treatment of Grave Diphtheria. G. Paiseau and P. Carrez—p. 710

*Serotherapy in Diphtheritic Paralysis. R. Cruchet and L. Ginestous—p. 725

Large Doses of Strychnine in Grave Diphtheria—Paiseau and Carrez report observations on the use of strychnine in grave diphtheria. Croup is the only contraindication to strychnine therapy. They emphasize that this treatment must be reserved exclusively for the grave forms and that strong doses can be employed only under careful medical supervision, which must be practically incessant. They use a 2:1,000 solution. The subcutaneous injections are given at three hour intervals. In cases in which moderate doses are given, five or six injections are used in the course of twenty-four hours, but to administer the strong doses, from seven to eight injections have to be given. In determining the doses, the tolerance of the subject as well as the gravity of the clinical form has to be considered. In the grave forms that are characterized by local signs of malignancy, extensive and perhaps fetid membranes and considerable cervical adenopathy, but in which generalized grave signs are absent, it is generally sufficient to administer 0.5 mg. of strychnine per kilogram of body weight in twenty-four hours. This dose must be reached in three or four days and may, if necessary, be increased to around 1 mg. With these doses the authors experienced not a single fatal accident. In the malignant anginas, in which the mortality is rather high, a dose of 1 mg. per kilogram of body weight for the twenty-four hour period is the minimum. After remarks about the so called supporting strychnine therapy for cases in which the diphtheria takes a rather slow course, the authors discuss associated treatments, pointing out that they always utilize the other classic treatments, such as total adrenal extract or epinephrine and especially ouabain, which is particularly helpful in case of appearance of signs of cardiac insufficiency. The use of digitalis preparations is advised against by some authors, since its association with strychnine supposedly increases the toxicity. Discussing the accidents of strychnine therapy and their treatment, the authors point out that in children the signs of intolerance to strychnine are not so characteristic as in adults. However, one of the signs that make advisable an arrest of the progression or a temporary reduction of the doses is the extension of the reflexogenic zones in the region of the knee reflexes. It is advisable to test these reflexes shortly before a strychnine injection is made.

Serotherapy in Diphtheritic Paralysis—Cruchet and Ginestous review the literature on serotherapy of diphtheritic paralysis. They cite Ferre's studies on avian diphtheria and show that these investigations became the basis of the serotherapy of diphtheritic paralysis. They differentiate two groups: (1) the associated paralyses, which develop in the course of the untreated or insufficiently treated cases of diphtheria, and (2) the isolated paralyses, which develop after the diphtheritic angina seems completely cured. In the latter cases the most frequent form of paralysis is that which ophthalmologists refer to as the paralysis of accommodation. They conclude that serum should be administered even in the isolated forms of diphtheritic paralysis, when the false membranes have already disappeared and the diphtheria is at least apparently cured. The serum should be administered in doses of from 40 to 60 cc. on the first days and should be decreased thereafter. However, only in exceptional cases is it advisable to exceed a total of from 100 to 200 cc. The intravenous injection (from 10 to 20 cc.) is to be recommended in grave cases. In the malignant forms the authors usually give simultaneously antgangrenous and antistreptococcus serum. All other treatments likewise can

be associated with the serotherapy. Depending on the circumstances, epinephrine, ouabain or strychnine sulfate may be given in the toxic forms with oliguria, physiologic solution of sodium chloride should be given by rectal drip.

*Low Leptomenigitides. Clinical and Therapeutic Studies on Fourteen Cases. Devic Ricard and M. Girard—p. 577

Leptomenigitides—Devic and his associates emphasize the increasing frequency of the low leptomenigitides among the syndromes of the cauda equina. They report clinical and therapeutic studies on fourteen cases. Anatomically the adherent process is most often encountered in the cystic type. The etiology of these syndromes is not completely clarified, it has never been possible to isolate precisely and incontrovertibly the local or general causes. From the pathogenic point of view the authors agree with Beriel that the physiologic process of sedimentation plays a part in the low localization of the infectious process. It is possible to distinguish a clinical form with scant symptomatology, pain being the only symptom. The authors emphasize the information derived from the study of the cerebrospinal fluid, presence of hyperalbuminosis and frequency of a slight cellular reaction. The progress of the iodized oil provides in the majority of cases interesting and exact diagnostic data. The mode of progression of the syndrome determines its individuality. The evolution is slow, but capriciously there are sudden exacerbations and veritable evolutive thrusts, after which there is a gradual diffusion and bilaterality of the signs. Phases of remission of several years' duration have been noted. From the diagnostic point of view, the identification of the syndrome of the cauda equina in most cases gives no serious difficulties. The true diagnostic problem is the differentiation between tumors of the cauda equina, the leptomenigitides and the diseases of the conus terminalis. To differentiate between these conditions it is necessary to pay attention to the distribution of the symptoms, to the mode of development of the syndrome and to information obtained from the lumbar puncture and from the progress of the iodized oil. The therapeutic problem is solved: it is the surgical intervention, which nevertheless has a more reserved prognosis in the leptomenigitides than in the tumors of the roots. The surgical results obtained by the authors are encouraging. Although occasionally not enough time had elapsed to judge the late results, they obtained five cures, four such considerable ameliorations as to be almost cures, generally permitting the patient to take up his work again, two arrests of the process, one of them partial, and, finally, three postoperative deaths, but one of these patients has a latent diabetes. These results although not perfect, give ample justification for the surgical treatment, the only effective therapeutic measure, internal medication and physical therapy being always ineffective. The authors admit that the spinal arachnoiditis is a much discussed problem, but in this report they study only the arachnoiditis of the cauda equina. To be sure, this low leptomenigitis may concur with forms that are localized higher up. They had occasion to observe two cases in which the two localizations coexisted.

*Simple and Efficacious Method of Oral Calcium Therapy. H. Fillion and P. Millischer—p. 1566

Developmental Disturbances of Hypophyseal Origin. M. Bariety—p. 1570

Simple Method of Oral Calcium Therapy—Fillion and Millischer say that the metabolism of calcium is not completely understood and that the dosage in calcium therapy is likewise still indefinite. It has been found that the degree of calcemia does not permit the estimation of the state of calcification or of decalcification of the organism. Moreover, the blood calcium exists in several forms, the most interesting of which, the active ionized form, is extremely difficult to estimate. The therapeutic procedure which the authors studied has the advantage

of being simple, efficacious and without danger. Their technique is the following: Into a flask of about 250 cc capacity, they place the finely crushed shell of an egg. They add the juice of two lemons and seal the flask hermetically. The contents of the flask are kept for about two hours at a temperature of 18 C. After thus the flask, which must still contain carbon dioxide, has to be opened. Its contents are filtered through gauze into a glass, into which a desired amount of sugar had been placed. The mixture is immediately taken by the patient, but depending on the patient's taste, some water may be added. The procedure can be employed for periods of from fifteen to twenty days, separated by short intervals. Discussing the elements that play a part in this therapy, the authors say that the egg shell consists chiefly of more or less phosphatized calcium carbonate. The lemon juice contains from 4 to 7 per cent of citric acid, also small quantities of alkaline citrates, of other organic acids and their salts, of mineral salts and of vitamins particularly of vitamin C, and of provitamin P. After making suggestions about the possible mode of action of the various substances, the authors discuss their therapeutic experiences with this method over a period of eighteen months. They employed it in various spasmodic disorders. They obtained favorable results in whooping cough, in spasmodic conditions such as tetany, in nervous irritability, and in colitis and other enteric disorders. In the last part of the paper they cite experiments on animals. In rabbits, which had been inoculated with the virus of rabies, it could be demonstrated that the administration of the preparation used by the authors retarded the development of the symptoms, whereas the administration of calcium gluconate or of the vitamin B₁ or C did not do this.

*Genesis of Sea and Automobile Sickness. W. Tobler—p. 1096

Genesis of Sea and Automobile Sickness—Tobler directs attention to the theory of sea, air and train sickness presented by Lenggenhager (see also abstract in *THE JOURNAL*, June 20, 1936, p. 2203), who demonstrated that the disturbances characteristic for sea sickness are not elicited by the labyrinth but rather by fluctuations in the pressure and traction exerted on the large sympathetic nervous plexus in the epigastric region. In the present report Tobler brings corroborating evidence for Lenggenhager's theory. A girl, aged 10, was subject to automobile sickness when traveling through the mountains, and the usual remedies were without avail. In accordance with Lenggenhager's suggestion to avoid pressure and traction on the viscera the child was placed prone on an upholstered board. During two hours of travel over mountainous roads the child remained free from all signs of automobile sickness. However as soon as the child left the prone position there was nausea and vomiting. When the prone position was resumed again the child again tolerated the automobile trip without difficulty. Similar observations were made on a boy aged 13.

*Influence of Menstruation on Elimination of Gonococcus. V. Puglisi—p. 659

Surgery of Ileocecal Tuberculosis. I. Radice—p. 663

Influence of Menstruation on Appearance of Gonococcus—Puglisi advises making bacteriologic examinations of the menstrual blood for the diagnosis of gonorrhea in women. In a group of twenty patients he found that gonococci are eliminated in the menstrual blood during the first and last days of menstruation. In the intermediate days the menstrual blood does not contain gonococci. The author believes that gonococci are concealed in the uterine tubular glands, which are stimulated to void during the first day of menstruation and also in the catamenial decidual cells and superficial epithelium of the uterine glands, which are eliminated on the last day of menstruation.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1937

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1927. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2226

For index to Organization Section see page 101B
